[13] Light Metals, Alunite—A New Source of Aluminum: Vol. 2, No. 14, March 1939, p. 115.

Digitized by Google

A recent report describes a process whereby ferruginous bauxite is treated with an excess of sulfur at high temperature and the resultant sulfides are chlorinated to yield aluminum chloride for use in the aluminum industry.[14]

The Carborundum Co. has announced a process for casting fused alumina refractories without a bond. A boroaluminate with a hardness of 7 to 7.5, high electrical resistance, and low thermal expansion is now being produced. In addition the company has devised a thermal microscope to study abrasive and refractory materials at temperatures above 2,000° C.[15]

The black appearance of aluminum utensils used in hot, slightly alkaline tap water has been found to be due to a purely optical phenomenon caused by a submicroscopic etching of the surface. As there is no superficial coating, corrosion resistance is unchanged. The etched surface has no hygienic or other disadvantages.[16]

Steel can be protected from corrosion by spraying, plate rolling, hot-dip plating, or calorizing aluminum on its surface.[17] The formation of the brittle compound $FeAl_3$ on plated steel can be avoided by the addition of a little silicon to the aluminum and by increasing the nitrogen and oxygen content of the steel. Aluminum can be deposited on iron and copper in a reducing atmosphere containing aluminum chloride gas at a temperature of 750° to 1,100° C. by the Martin process.[18]

The story of the production and uses of aluminum and its products is depicted in two motion-picture films recently produced by the Bureau of Mines in cooperation with the Aluminum Co. of America.

## WORLD BAUXITE AND ALUMINUM INDUSTRIES

### BAUXITE PRODUCTION

World production of bauxite in 1938 advanced slightly from the previous record established in 1937. The 1938 output is estimated as 3,850,000 metric tons, an increase of 5 percent over 1937. The principal producing countries, in the probable order of importance, were: France, Hungary, British Guiana, Yugoslavia, Italy, Surinam, the United States, the U. S. S. R., and Netherland India. Estimates for 1938 indicate that British Guiana increased its bauxite production approximately 51 percent, Hungary 20 percent, the U. S. S. R. 17 percent, Netherland India 16 percent, and Yugoslavia 12 percent.

## ALUMINUM PRODUCTION

The world production of aluminum in 1938 exceeded the 1937 record by approximately 17 percent. Production in 1938 is estimated as 561,800 metric tons. Germany took the lead as the foremost producer in 1938, increasing its output approximately 27 percent over 1937, whereas the United States, leader in 1937, decreased its output 2 percent. Japan increased its output 44 percent over 1937, Canada 32 percent, France 25 percent, the United Kingdom 24 percent, Norway 22 percent, the U. S. S. R. 20 percent, Switzerland 17 percent, and Italy 13 percent. The world's capacity for producing aluminum is expected to reach 840,000 tons by 1940.[19]

## ALUMINUM CONSUMPTION

According to the Metallgesellschaft world consumption of aluminum in 1937 totaled 501,700 metric tons, a 26-percent increase over 1936. Europe consumed 63 percent of the total. The apparent consumption of the seven largest users of aluminum in 1938 (partly estimated) was as follows: Greater Germany 161,000 tons, the United States 81,213, the United Kingdom 66,000, the U. S. S. R. 56,000, Japan 40,000, France 30,000, and Italy 28,000. The United States was the only large world consumer to show a decline (47 percent) in 1938.

## REVIEW BY COUNTRIES

*Brazil.*—Bauxite reserves of the Poços de Caldas Plateau,[20] chiefly in Minas Geraes, are conservatively estimated at 20,000,000 metric tons. The Companhia Geral de Minas, the principal producer, washes, crushes, dries, pulverizes, and packs in bags the bauxite that it exports to Buenos Aires, Argentina, for the manufacture of aluminum sulfate. The ore shipped averages 60 to 65 percent $Al_2O_3$, 1 to 2 percent $SiO_2$, 4 to 6 percent $Fe_2O_3$, 1 to 2 percent $TiO_2$, and 28 to 31 percent combined water. However, about 90 percent of the Poços de Caldas ore averages only 54 to 60 percent $Al_2O_3$, 2 to 5 percent $SiO_2$, 7 to 10 percent $Fe_2O_3$, 1 to 2 percent $TiO_2$, and 28 to 32 percent combined water. The large bauxite deposits near Ouro Preto, also in Minas Geraes, are soon to be mined by the Companhia Electro-Chimica Brasileira.

Favorably located bauxite deposits are being prospected in the state of Rio de Janeiro near Itatiaya,[21] which is close to a railroad. The M. C. Fonseca e Companhia, operating the Muquy deposits,[22] João Pessoa County, Espirito Santo, recently began to ship crushed ore by rail to Rio de Janeiro. There are large reserves of bauxite in five other States in Brazil, but they have not been developed. In Maranhão about 10,000,000 tons of bauxite occur on Trauhyra Island and along both banks of the Gurupy River.

Although railroads are near some of the Brazilian bauxite deposits, transportation is a problem because of the shortage of freight cars and the differences in gage of track. Thus, the low cost of mining ($0.55) and processing ($2.42) is offset by the high cost of freight and loading, and the total cost of delivering processed bauxite, f. o. b. Santos, is about $7 per metric ton. The ore sells for $8.80 to $11.00 per ton, f. o. b. Santos, and $6.60 to $9.90, f. o. b. Rio de Janeiro.

*British Guiana.*—The 1938 production of the Demerara Bauxite Co., Ltd., in the Christianburg-Akyma field, totaled 454,549 metric tons of bauxite containing 60 percent $Al_2O_3$ and 117,502 tons of lower-grade ore (mostly 30 to 50 percent $Al_2O_3$). The Berbice Co., Ltd., affiliated with the American Cyanamid & Chemical Corporation, obtained a concession on 4,000 acres of bauxite land about 125 miles up the Berbice River from New Amsterdam. Other foreign bauxite holdings of the chemical concern are in the Para district, Surinam. A recent bulletin [23] on the British Guiana bauxite deposits describes

a fairly reliable field test, based upon loss on ignition at a red heat, to distinguish gibbsitic bauxite from lithomarge or other indurated earths and clays.

*British India.*—The Aluminium Production Co. (India), Ltd., (Indian capital) plans to construct an aluminum-reduction works near Asansol, Bengal, and a rolling mill at Belur. Coal is available near Asansol, and bauxite may be obtained from the Ranchi district, Bihar and Orissa. Aluminium, Ltd. (Canadian), and the British Aluminium Co., Ltd., jointly propose to erect similar facilities in India.

*Canada.*—Exports as well as production of aluminum established a new record in Canada in 1938. Exports totaled 58,717 metric tons compared with 44,000 tons in 1937. Of the 1938 exports, 30,765 tons went to the United Kingdom, 14,105 to Japan, 5,621 to Germany, 1,934 to the U. S. S. R., 1,620 to Sweden, 1,518 to China, 1,013 to the United States, and 890 to Norway. Some shipments to Japan were sent via Portland, Maine. Canadian imports of bauxite, alumina, and cryolite increased from 282,093 metric tons in 1937 to 339,949 in 1938. British Guiana bauxite comprised 84 percent of the total imports.

Expansion of the aluminum-reduction and alumina plants of the Aluminum Co. of Canada at Arvida, Quebec, was completed in 1938. Fabrication facilities are to be extended at Toronto to provide for more products used in the aircraft industry. In 1938 the hydroelectric properties and power sites on the Saguenay River belonging to Alcoa Power Co., Ltd., were sold to the Aluminum Power Co., Ltd., a subsidiary of Aluminium, Ltd.

*China.*—The Hsin Chung Kungssu (Japanese) has obtained permission from the Kailan Mining Administration to exploit bauxite deposits in North China. Large deposits are said to occur in Kaiping, Tzechwan, and Poshan.

*France.*—The capacity of French aluminum-reduction plants is to be expanded from 45,000 to 55,000 metric tons in 1939.[24]

The capacity of the alumina plant at La Barasse was expanded in 1938. Of 13 companies in France, 4 produce most of the bauxite output.[25] The underground and open-pit mining methods employed in the bauxite mines were recently described.[26]

Bauxite exports totaled 291,684 tons in 1938 (301,601 in 1937), of which the United Kingdom received 187,963 tons, Germany 84,075, and Sweden 13,923. Alumina exports totaled 21,770 tons (27,158 in 1937), of which Switzerland received 16,026 and Norway 5,264. Exports of crude and semicrude aluminum increased from 9,031 tons in 1937 to 16,560 in 1938.

*French Guinea.*—The bauxite deposits on the isle of Tamara in the Los Islands group, estimated to contain 20,000,000 tons, were developed in 1938 by Société Anonyme des Bauxites du Midi (Canadian). A geological survey of the vast bauxite resources on the mainland of French Guinea[27] is to be made.

Digitized by Google

*Germany.*—Although the largest producer of aluminum in 1938, Germany had to import an additional 14,521 metric tons of crude metal (only 3,645 tons in 1937) to serve domestic requirements. The import duty on aluminum was lifted until March 31, 1939. Exports of crude metal increased from 1,334 to 2,831 tons, but those of fabricated metal decreased from 15,920 to 15,096 tons.

The State-owned Vereinigte Aluminiumwerke A. G. produced approximately three-fourths of the total German aluminum output at Lautawerk, Toging-am-Inn, and Grevenbroich (Niederrhein); the balance was produced by Aluminiumwerke G. m. b. H. at Bitterfeld and Aluminium G. m. b. H. at Rheinfelden (Rhein). In 1938 the capacity of the Rheinfelden plant was extended to 23,000 tons annually, a new aluminum-refining plant was constructed at Lautawerk, and expansion of the Austrian aluminum-reduction plants at Steeg and Lend was contemplated. Reports state that in 1939 approximately 8,000 tons of alumina will be produced from clay at the large-scale experimental plant built at Lippe. Although the recovery of alumina from clay is costly, this source of supply can be relied upon in an emergency.

Bauxite imports dropped from 1,313,152 tons in 1937 to 1,184,647 in 1938. Of the 1938 imports, 363,256 tons came from Hungary, 348,068 from Yugoslavia, 192,668 from Netherland India, 96,593 from Italy, 92,272 from France, 84,796 from Greece, and 6,994 from Denmark (probably cryolite). Imports from Netherland India increased 39 percent compared with those in 1937, whereas imports from Hungary, Yugoslavia, and Italy decreased substantially. Bauxite deposits in the Laussa Valley of German Austria may be mined in the future.

*Hungary.*—The large bauxite production of Hungary (reported at 540,717 metric tons in 1938) is derived from two open-pit mines worked near Gánt by Aluminiumérc, Bánya és Ipar R. T. of Budapest. Here a continuous layer of red bauxite, from 50 to 100 feet thick, is underlain by an uneven surface of Triassic dolomite and overlain in part by Tertiary clay and limestone strata of varying thickness. Faults have been important in localizing the bauxite areas, having preserved them from recent erosion.[28] Another aluminum-reduction plant with an annual capacity of 1,000 tons is to be completed in 1939 near Totis by the Hungarian United Coal Mining Co., Ltd.

*Indochina.*—The bauxite produced in Indochina, probably derived from the Dragon mine in the Province of Lang-son, is exported to Japan.[29]

*Italy.*—The aluminum-reduction plant of the Società Alluminio Italiano (Canadian) at Borgofranco d'Ivrea will be expanded to an annual capacity of 4,000 tons in 1939. The capacity of synthetic cryolite and alumina plants at Porto Marghera also are to be increased. In 1938, Italy exported 75,386 metric tons of bauxite to Germany and 39,616 tons of alumina, chiefly to Switzerland and Germany. The Società Bauxiti Istriane (a Montecatini subsidiary) began mining bauxite near San Giovanni (Apulia), southern Italy. In recent years almost all the bauxite has come from Istria.

[28] Singewald, Quentin D., Bauxite Deposits at Gánt, Hungary: Econ. Geol., vol. 33, No. 7, November 1938, pp. 730–736.

[29] Génie civil, "Les nouvelles substances minérales exploitées en Indochine. La Bauxite: Paris, vol. 112, No. 10, March 1938, p. 214.

Digitized by Google

*Japan.*—The nationalization of the electrical industry of Japan is expected to result in large extensions and consolidations in aluminum and magnesium production facilities. The Japan Aluminium Co. plans to increase aluminum output at its Takao plant from 6,000 to 8,000 metric tons, and construction has begun on a new reduction plant of 8,000 tons annual capacity at Beiron, Karenko City, East Taiwan.[30] With the financial backing of large Japanese industrial and power concerns and protection of the government, the Japan Light Metals Co. proposes to erect alumina and aluminum plants in several parts of Greater Japan. The proposals call for an alumina plant of 120,000-ton annual capacity at Shimizu and an aluminum-reduction works at Kambra, both in Shizuoka Prefecture. The Nitto Chemical Industrial Co. plans to utilize an aluminous phosphate ore from Manchuria in the production of aluminum at Hachinohe, northeastern Japan. Alumina will be extracted from the ore by treatment with sulfuric acid and ammonia gas.

The Japanese producers of aluminum[31] in 1938, in their probable order of importance were: Japan Aluminium Co., Takao, Formosa; Japan Electric Industry Co., Omachi and Yokohama; Sumitomo Aluminium Reduction Co., Niihama; Nichiman Aluminium Co., Iwasemachi; Japan Soda Co., Ltd., Takaoka; and probably the Manchuria Light Metal Co., Fushun, Manchuria. Production is estimated at 13,000 tons compared with 9,000 tons in 1937. More than 21,500 tons of aluminum were exported to Japan in 1938 from Canada, Norway, Germany, and the United States, and consumption of domestic and imported primary and secondary metal probably exceeded 40,000 tons. In Northeastern Korea the Chochinko Hydro-electric Co. began constructing a 220,000-volt transmission line 100 kilometers long with aluminum cable, steel-reinforced.

*Netherlands.*—In 1938 the N. V. Aluminium Walswerken-en Persbedrijven (Canadian-Dutch) began to erect an aluminum rolling and extrusion plant at Utrecht, at the crossing of the projected Amsterdam-Rhine Canal and the new locks in the Old Rhine. The same interests also formed a company for the production of aluminum, but construction of the reduction plant has not yet started. Interests representing L'Aluminium Français S. A. (French) were denied the privilege of establishing a rival aluminum industry in the Netherlands. The increasing use of aluminum and the geographical position of the Netherlands as a distributing center are given as the reasons for creating the aluminum industry rather than the desire to satisfy the small local consumption (2,307 metric tons of crude and semicrude metal imported in 1938).

*Netherland India.*—The N. V. Nederlandsche-Indische Bauxiet Exploitatie Maatschappij (NIBEM) produced an estimated 230,000 metric tons of bauxite in 1938 on the island of Bintan, where construction was completed on a bauxite washing and drying plant and on an overhead cableway connecting it with the new bauxite deposits on the islands of Angkoet and Kojang.

Early in 1939 the N. V. Billiton Maatschappij, the parent concern of NIBEM, and the N. V. Gem. Mijnbouwmij Billiton sought capital to establish an aluminum industry in Netherland India. Preliminary plans call for the construction of an alumina plant, probably at

[30] Bureau of Mines, Mineral Trade Notes: Vol. 8, No. 1, Jan. 20, 1939, p. 2.

Digitized by Google

Palembang, Sumatra, near the Boekit Asem coal mines; an aluminum-reduction works on the east coast of Sumatra which can utilize the water powers of the Asahan River; and fabricating works in Java at Djokjasche.

*Norway.*—In 1938 imports of bauxite into Norway totaled 25,942 metric tons (40,474 in 1937) and of alumina, 43,738 tons (38,016 in 1937). Exports of crude aluminum increased from 21,503 tons in 1937 to 28,577 in 1938, of which 5,325 tons went to the United Kingdom, 5,014 to Japan, 3,190 to the U. S. S. R., 2,700 to Greater Germany, 2,610 to Sweden, 2,427 to the United States, and the rest chiefly to Denmark, Switzerland, Czechoslovakia, Belgium, and Brazil.

*Poland.*—An aluminum-reduction works is to be constructed near Sandomir.

*Surinam (Dutch Guiana).*—In 1938 the Surinaamsche Bauxite Maatschappij shipped 377,595 metric tons of bauxite from its mines at Moengo Hill on the Cottica River. Another bauxite property is to be developed by the company in 1939 in the Para district about 25 miles south of Paramaribo. Bauxite mined at Topibo Hill will be transported by narrow-gage railroad to a crushing, washing, screening, and drying plant to be constructed on the west bank of the Surinam River. Two rotary drying kilns are to be installed with a total capacity of 150 tons per hour. As heretofore, the company will pay a royalty of 12½ cents per ton on bauxite mined and contribute 10 cents per ton on each ton exported, for harbor and river maintenance.[32] The N. V. Billiton Maatschappij is investigating bauxite deposits in the Nassau Mountains and along the Government Railroad, 70 miles south of Paramaribo.

*Sweden.*—The AB. Swenska Aluminiumkompaniet, operating the aluminum-reduction works at Mânsbo, plans to establish an alumina plant in Sweden.

*Switzerland.*—The Neuhausen Co. (AIAG) increased its output in 1938 at Chippis and started producing aluminum of 99.99-percent purity. Outside of Switzerland the capacity of company plants was increased in Greater Germany and Italy, and an interest was obtained in a new aluminum-reduction works under construction in the United Kingdom. Its plants in France were handicapped by labor difficulties. The Lend (Austria) reduction works probably will be converted into an independent subsidiary, as was done at the Rheinfelden (Germany) works.

In 1937 the Aluminum Cartel, the Alliance Aluminium Cie. (Basel), liquidated its available stock and abolished output curtailment measures. Since then European demand for aluminum has been greater than the supply.

*Unfederated Malay States: Johore.*—Bauxite mined at the Pasir mine, Batu Pahat, is exported to Japan by the Ishiwara Sangyo K. K. The area in the vicinity of Kuantan, Tanjong, and Changkat Pandan in Pahang is being prospected for bauxite.

*U. S. S. R.*—In 1938 the Volkhov and Dnepr aluminum-reduction plants produced about 44,000 metric tons of metal compared with 40,000 in 1937. The alumina process at the Dnepr works was modified, and preparations were made for the utilization of nepheline at the Tikhvin alumina works. Improvements were made in the

[32] American Metal Market, New York, vol. 45, No. 103, May 27, 1938, p. 5.

Digitized by Google

recovery of alumina from bauxite (70-percent recovery) and in the consumption of electric energy per ton of aluminum produced. In 1939 the Government plans to invest considerable capital in the industry and obtain higher efficiency in the use of raw material, power, and labor. The new alumina and reduction plants at Kamensk are scheduled to start operations in 1939. A modern, closed-type reduction furnace, with self-baking electrode operating on 50,000 amperes, will be employed.[33] Before 1942 new aluminum works are to be constructed in Kandalaksha and at Rybinsk, Siberia.

The bauxite deposits in the North and South Urals and near Tikhvin produced an estimated 270,000 tons in 1938. New bauxite discoveries are reported in the Bashkiria Republic, at Aktiubinsk east of the Urals, and near Tula, Central Russia. The All-Union Institute of Heat Technology reports that 23 to 40 percent alumina could be recovered from Soviet lignite ashes.

*United Kingdom.*—Imports of crude aluminum and its alloys into the United Kingdom totaled 46,996 tons in 1938 compared with 32,079 in 1937. Of the 1938 imports, 30,902 tons came from Canada, 9,699 from Switzerland, and 5,434 from Norway. Imports of bauxite increased from 222,953 tons in 1937 to 252,925 in 1938.

During 1938 the British Aluminium Co., Ltd., continued its program announced in 1937 of expanding alumina and aluminum production capacity. The alumina plant at Burntisland, Scotland, was completed and is working at full capacity to meet demands of the new reduction furnaces at Lochaber, Scotland. The alumina plant at Newport, Wales, was nearly completed, and fabrication facilities at Banbury, England, are being extended considerably. Aluminium, Ltd., established a research laboratory at Banbury in 1938. British, Canadian, and Swiss interests formed the South Wales Aluminium Co., Ltd., which began to construct an aluminum-reduction plant early in 1939 at Resolven in the Neath Valley, Glamorganshire, South Wales.

*Yugoslavia.*—The capacity of the new reduction plant at Lozovac near Sibenik is to be increased to 2,000 tons of aluminum annually. Most of the metal has been exported to the United Kingdom. Another alumina plant (in addition to the one at Ljubljana) is under construction at Lozovac by Aluminiumfabrik A. G. In 1938 the Dalmacia-Bauxit Co. of Split began to work a new bauxite deposit at Donja Suhaja, near Bosanska Krupa; and two new bauxite mining companies, the Pan Bauxit Co. (German) and the Ugrovaca Mining Co. of Zagreb (Swiss), began exploration work in the Siroka Breg Mountains near Mostar.

| Report on strategic minerals | 656 | Review by States | 662 |
| Health hazards | 660 | Foreign trade | 665 |
| Stocks | 660 | World production | 666 |

Normal international trade in mercury was hampered again in 1938 by the civil war in Spain, where the principal mercury reserves of the world are situated. Although the war continued to restrict production in Spain, world supplies of metal were more than ample for consumption requirements even though demand in Germany and the United Kingdom surpassed the high rates attained in 1937. Italian production duplicated the record rate achieved in 1937, but exports dropped from 67,075 flasks in 1937 to 55,327 in 1938. Exports from Spain were reported to have increased from 28,357 flasks in 1937 to approximately 40,000 in 1938, so indications are that Spain supplied a larger share of world requirements in 1938 than in 1937. Consumption in the United States was markedly lower in 1938 with production only 9 percent above the 1937 rate and imports 88 percent less than in 1937. Another source of foreign metal for consumption, which is not revealed by import statistics, is the mercury produced in this country from concentrates received from Mexico. Metal from this source totaled more than 2,600 flasks in 1938. In addition, actual consumption of mercury in the United States probably was higher than available figures indicate owing to a reduction in consumers' stocks. Consumers' stocks are believed to have been built up considerably during the late months of 1936 and early in 1937, when a world shortage of metal, which never materialized, was threatened.

The year 1938 was marked by the strenuous efforts of the Rebel forces in Spain to win possession of the Almaden mine and by the stubborn resistance of the Loyalist forces. The stiffening of prices early in 1939 probably was due partly to additional demands for mercury caused by world-wide fear of war. It also suggests that the defeat of the Loyalist Government forecasts closer cooperation between Italian and Spanish producers in regard to the marketing of supplies rather than a return to the competitive methods that prevailed before the formation of Mercurio Europeo.

Although to most domestic producers, 1938 was unsatisfactory, the situation at the end of the year was much more favorable than at the beginning. In January 1938 consumption was low and prices were falling. In December, on the contrary, demand was improving and prices were rising.

Digitized by Google

Notes on advances in the metallurgy of quicksilver since the World War were published by Ransome [1] early in 1939.

Wehrly [2] has prepared an article that contains much information on uses of mercury. Regarding specifications for mercury, Wehrly states:

The relative low tenor of cinnabar ores—8 percent in Spain, ½ to 2 percent in Italy, 1 percent in Mexico, and less than ½ percent in the United States—precludes transportation to a custom smelter, hence the mine must be a complete unit. The only exception is a recent experiment in which hand-picked Mexican ore was sent to this country for reduction.

The quality of the mercury so produced is exceptionally pure. Random assays show well over 99.5 percent and as high as 99.9 percent with dirt and oil from the insides of the flask as the only mechanical impurities. It is peculiar that no standard has been set by the industry—a fact probably caused by this unusual degree of purity. The U. S. P. states that mercury should test at least 99.5 percent. One large user, who if he actually received such impure metal would reject it, calls for 95 percent. Conversely another company has set up specifications which cannot be met with commercial metal. Further purification is not necessary in the majority of cases, and mechanical cleaning will suffice. Commercial mercury is termed "prime virgin" and is packed in iron or steel flasks containing a net weight of 76 pounds (34.5 kilograms). Exceptional uses may require redistilled or triple-distilled mercury, in which latter case the purity exceeds 99.9 percent plus with a nonvolatile content of not over 0.002 percent. The redistilled type is sold in earthenware or glass jugs containing 5, 10 or 20 pounds.

United States Patent 2,119,231, issued May 31, 1938, covers a process for recovering mercury from antimony-bearing ores.

## REPORT ON STRATEGIC MINERALS

A joint report on certain deficient strategic minerals was prepared by the staffs of the Geological Survey and the Bureau of Mines and published in February 1939. Because of the importance of strategic minerals and the interest in them, particularly at present, the text on mercury and two historical tables are quoted as follows:

*General.*—The normal annual consumption of mercury in the United States in recent years has ranged from 25,000 to 35,000 flasks of 76 pounds each, of which about half has been imported. Mercury is used in the manufacture of fulminate,

for detonating high explosives and fixed ammunition, for gold recovery by amalgamation, in drugs (calomel, corrosive sublimate, etc.), dental amalgam, antifouling paint for ship bottoms, storage batteries, barometers, etc. Substitutes for some of these purposes may be used, but none is known for the greater part of the consumption.

*Production, imports, exports, and apparent new supply of mercury in the United States, 1910–38, in flasks of 76 pounds*

*Sources.*—Mercury mining in the United States began in California about 1846, and for many years deposits in that State yielded all of the domestic production. Even though many deposits in other States have been productive (chiefly Texas, Oregon, and Nevada), the mines in California consistently ship more than those of any other State. For most of the years from 1850 to 1870, a single mine (New Almaden) yielded 70 to 90 percent of the output of California, which was almost the entire domestic production. Domestic production attained the annual maximum of 80,000 flasks in 1877, and from 1880 to 1919 it generally ranged from 20,000 to 35,000 flasks. Prior to 1919, domestic production usually yielded a surplus for export, but since then imports have generally been needed to meet consumption. During the last 5 years (1933–37) production and imports have been about equal. An import duty on mercury was first imposed in 1883, and since 1922 it has been 25 cents a pound or $19 a flask.

The principal mercury mineral is the sulfide, cinnabar, and the recovery processes are designed to extract mercury only, since mercury is rarely present in the ores of the other metals. As almost every mine is equipped with a recovery plant, metallic mercury is shipped direct to the market, and mine production tends to respond quickly to changes in price. The ore bodies have diverse shapes and sizes, but most of them are tabular and dip steeply into the earth. All mines yield some high-grade ore, but the steady decline in grade through the years has necessitated improvements in mining and treatment. Most of the ore now treated at domestic mines contains from 3 to 10 pounds of mercury per ton of ore.

Several efforts have been made to appraise the reserves of mercury in some Western States. One estimate made in 1931 indicated about 175,000 flasks in six States, but from 1931 to 1937, inclusive, nearly 115,000 flasks were produced. It is unusual to find blocked-out reserves in any mercury mine, and for this reason it is almost impossible to estimate mercury resources with any degree of accuracy. Three active districts in California and one in Nevada were studied by Federal geologists in 1938. A study of the history of production at numerous mines, taking into account their geologic features and environment, as well as prevailing technique and prices, indicates that dependable forecasts of production at several assumed prices can be made.

*Production from domestic mines.*—The latest summary of the mercury deposits of California (1918) records about 125 mines or groups of mines, as well as many more prospects, in 39 counties; practically all of the output, however, has been

Digitized by Google

derived from seven counties. One mine (New Almaden) has yielded nearly half the total of the State, but it has been idle in recent years. The peak of production appeared in 1877, and the peaks for the six outstanding counties appeared between 1865 and 1881. Even though it cannot be stated that no new large deposits will be discovered, it appears unlikely that the output of domestic mines will approach again the record for 1877. Experience in most mines shows that the grade of ore treated has steadily declined and now rarely exceeds 10 pounds of Mercury to the ton. In many mines the tenor of most of the ore ranges from 3 to 5 pounds to the ton. Without the benefit of the tariff of 25 cents a pound, imposed in 1922, it is doubtful whether any mines in the State would be active.

[1] Includes, in addition to States shown as "[2]", Alaska, Arizona, Arkansas, Idaho, Utah, and Washington.
[2] Included with "Other States." Bureau of Mines not at liberty to publish figures separately.

Since 1897, several thousand flasks of mercury have been produced annually from a district of several square miles in area near Terlingua, Tex. Although several mines have been developed in this district, most of the production of about 137,000 flasks has come from one mine.

Mercury was discovered in Oregon as early as 1865, but the State did not become important as a producer of mercury until 1927. Since then, annual production has been fairly constant, and the number of sources has risen steadily. From a recent study of the deposits throughout the State, it appears that if present prices are maintained the current rate of production may be expected to continue for a decade or more.

Even though mercury is recorded widely in Nevada, most of the exploration is confined to 32 districts; of these, only 7 have yielded a product and 2 have yielded well over one-half of the total production. Except in times of high prices, production is small.

Since 1910, annual production has responded closely to price, but the highs and lows of production follow those of price by a year or two.

*Technologic progress.*—Technologic advance in the mercury industry has made it possible to treat ores of successively lower grades. In 1875 the principal domestic producer was the New Almaden mine in California, and the grade of ore produced there averaged 3.35 percent or 67 pounds of mercury per ton. By 1910 the average yield of all ores treated in the United States had declined to 0.63 percent (12.6 pounds), and in recent years it has approximated 0.40 percent (8 pounds). Not all of this decline in grade, however, can be ascribed to technologic improvement, because it is also due in part to the rise of prices resulting from the tariff, first imposed in 1883 and substantially increased in 1922, which has made possible the mining and treatment of lower-grade ores.

Since the World War, production has been derived from an increasing number of small mines. Some of the new developments in mine mechanization have not been applicable to mercury mines because these were too small to warrant the capital investments required. Mercury does not occur typically in extensive low-grade disseminated deposits, so that there is little possibility of applying the large-scale mass production methods used, for example, in copper mining.

Improvement in metallurgical practice has increased recovery and reduced costs in treating mercury ores. The introduction of the Scott furnace in 1875 at New Almaden, Calif., is perhaps the most significant improvement in an art that has been practiced for centuries. This invention permitted continuous treatment of ores and the use of fine sizes which hitherto had been difficult to handle. Subsequently, the need for still lower costs and greater tonnages led to the introduction in 1916 of mechanical furnaces of the multiple-hearth and rotary-kiln types, which now are widely used in the domestic industry. Retorts, which were used extensively prior to 1875, are now employed only for the treatment of special byproducts at furnace plants or at small mines where the high first cost of the more efficient smelting units is not justified. Concentrating methods for treating low-grade ores have not been developed to any great extent, and many authorities believe that improvement in this direction will be limited.

Summarizing, the technique of treating mercury ores has advanced considerably in recent years. Doubtless, additional improvement will be made, but it is believed that the art is approaching maturity and that if technology is to maintain production at the present level it will have to do so through improvements in methods of finding new ore bodies.

*National requirements.*—The principal military uses for mercury are in the manufacture of fulminate for detonating high explosives, drugs (calomel, corrosive sublimate, etc.), dental amalgam, and antifouling paint for ship bottoms. The apparent consumption of mercury was nearly 24,000 flasks annually in the 5-year period 1912–16. In the war years, 1917–18, consumption averaged 33,000 flasks, or 38 percent higher. The apparent annual consumption for the 10 years ending 1937 amounted to 28,000 flasks. From 1926 to 1929, however, and in 1936 and 1937, consumption exceeded 30,000 flasks. Thus future domestic requirements under normal conditions may be estimated at 35,000 flasks per annum. Assuming an increase of about one-third during a war emergency, the requirements would probably approximate 46,000 flasks annually.

On April 3, 1939, the Senate passed a bill which provides $10,000,000 a year for 3 years, 1940 to 1943, for the purchase of strategic and critical materials for stockpile purposes. A similar bill, which, how-

Digitized by Google

ever, provides a total of $100,000,000 in 4 years, has been reported to the House by the House Military Affairs Committee.

## HEALTH HAZARDS

Mercury poisoning has been discussed at length by Neal.[3] Neal listed industries with potential mercury hazards as including the mining of cinnabar, gold, and silver; chemical manufactures of mercury compounds, also of cyanogen and electrolytic chlorine; manufacture of alloy and amalgam; electrical industries of several types; the felt industry; dentistry; chemical and physical laboratories; the manufacture of pharmaceuticals and explosives; decoration of china and porcelain; photography; certain phases of the printing industry; paints; engraving; jewelry; mercury boilers; dry-battery manufacture; gilding; bronzing; and the hardening of steel tools by quenching in mercury. He says mercury poisoning may develop from introduction of mercury through four routes: (1) Inhalation of vapor or dust, (2) ingestion, (3) the skin, and (4) subcutaneous tissues. The first route is the common one in industrial mercury poisoning. The symptoms of the two types of chronic mercury poisoning, threshold dosages, diagnoses, and prevention are discussed.

Prevention of mercury poisoning is described in General Electric Co. Handbook GEQ–104, which gives results of the company's experiences and quotes from Bureau of Mines Bulletin 222[4] and other sources. The General Electric Co. has developed a mercury vapor detector through which vapors invisible to the human eye cast an ultraviolet shadow. An extremely low ratio of mercury to air (as little as 1 part mercury to 1 billion parts of air) casts the shadow distinctly.

## STOCKS

Reliable information indicates that there were no stocks at Spanish ports at the end of 1937 and that little metal was on hand at the Almaden mine. Roura & Forgas were reported to have had 22,000 flasks of mercury in stock in London at the end of 1937. Italian inventories were believed to have been low at that time. Additions were made to Italian stocks in 1938 by the large excess of production over exports, but further data are lacking concerning the other centers. Producers' stocks in the United States were not much in excess of 1,000 flasks at the end of 1938, and stocks in domestic warehouses totaled 553 flasks.

## PRICES

The average quoted price for quicksilver at New York in 1938 was 16 percent below that in 1937. Demand was low as the year began, and the average monthly price declined from $79.24 in January to $71.02 in April, the lowest monthly price for the year. Large purchases by a San Francisco bank in April and May, purported in the trade to range from 2,000 to 2,500 flasks, were partly responsible for the rapid advance to $80.73 in June, the highest level of the year. The price declined after June to $73.48 in October then advanced to $76.77 in December, and the upward movement of prices continued

in 1939. Demand abroad was better than in this country, consequently the New York and London price differential was lower in 1938 than at any time since 1931, when the United States had an excess of production and exported relatively large quantities of metal. The London price fell only 4 percent compared with a 16-percent decline in New York, thus the differential between New York and London prices was only $8.55 in 1938 compared with $20.53 in 1937. The domestic tariff is $19 a flask.

*Average monthly prices per flask (76 pounds) of mercury at New York and London and excess of New York price over London price, 1936–38*

## CONSUMPTION AND USES

Figures covering the available supply of mercury in 1938 indicate that consumption declined sharply from 1937. Although the rate of consumption was lower in 1938, the use of metal obtained from foreign ores, which are not covered by import statistics or domestic production figures, and possible withdrawals from consumers' stocks resulted in actual consumption being considerably above apparent consumption.

The General Electric Co. reports that a new mercury boiler, which will require 100,000 pounds of metal, will be installed in 1939. It estimates that an additional 4,000 to 5,000 pounds of mercury will be required in 1939, principally for mercury lamps and mercury switches.

Lignasan is a product made by du Pont for use in controlling sap stain in the timber industry, in which the active ingredient is 6.25 percent ethyl mercury chloride, equivalent to slightly less than 5 percent metallic mercury. A new Lignasan, claimed to be superior to the older type, contains 6.25 percent ethyl mercury phosphate.

During 1938 the completion of fluorescent lamps with 3 to 10 times the efficiency of Mazda lamps was announced. In these units an arc is maintained between electrodes in the ends of evacuated glass tubes. Mercury vapor sustains the arc.

A new wall-type mercury switch may consume a fair quantity of metal.

Digitized by Google

A submersible turbine pump has been developed in which the water is sealed out at the top by mercury in a rotating cup attached to the motor shaft.

Two new fungicides were announced early in 1939 by Mer-Q-Ree, Inc.—Mer-Q-Ree for use in exterior paints and R888 (mercury fill) for use in interior paints. Both are furnished in semiliquid form and are described as easily miscible.

An artificial minnow that contains a small quantity of mercury to make it wiggle in a lifelike manner as it is trolled through the water is being manufactured by the Mercury Bait Co. of Cleveland.

## REVIEW BY STATES

Output of mercury in the United States in 1938 increased 9 percent over the relatively stationery production in 1937 and 1936. The gain in 1938 was due mainly to larger production by the New Idria, Mount Diablo, Mirabel, Oat Hill, and Great Western mines in California and by the Bonanza mine in Oregon, which more than offset the closing of the Oceanic mine in midyear, the idleness of the Big Bend mine, and reduced activity at other Texas properties, as well as lower production at some of the properties that remained active most or all of 1938. California's output rose from 9,743 flasks in 1937 to 12,277 in 1938, and its share of the total jumped from 59 percent to 68 percent. Oregon, the second largest producing State, increased its output from 4,264 to 4,610 flasks, while its share of the country's total was 26 percent, as in 1937. Production in Nevada remained unimportant, but activity in the Bottle Creek district was claimed to point the way toward greater production in the future. Alaska also produced some metal in 1938 and anticipated expansion. Output in Texas declined in 1938. Arkansas failed to increase production in 1938, and Washington's output remained insignificant. The principal producing mines in 1938 were as follows: California: Contra Costa County, Mount Diablo mine; Lake County, Great Western, Mirabel, and Sulphur Bank mines; Napa County, Oat Hill mine; San Benito County, New Idria mine; San Luis Obispo County, Klau and Oceanic mines; and Sonoma County, Cloverdale mine. Oregon: Douglas County, Bonanza mine; Jefferson County, Horse Heaven mine; Lane County, Black Butte mine; and Malheur County, Opalite mine. Texas: Brewster County, Chicos and Rainbow mines. These 15 mines produced 90 percent of the country's total compared with 86 percent by the 15 principal mines in 1937.

*Mercury produced in the United States, 1937–38*

| Year and State | Producing mines | Flasks of 76 pounds | Value [1] | Year and State | Producing mines | Flasks of 76 pounds | Value [1] |
|---|---|---|---|---|---|---|---|
| 1937 | | | | 1938 | | | |
| Arizona | 3 | 37 | $3,337 | California | 52 | 12,277 | $926,545 |
| California | 54 | 9,743 | 878,624 | Nevada | 17 | 336 | 25,358 |
| Nevada | 20 | 198 | 17,855 | Oregon | 13 | 4,610 | 347,917 |
| Oregon | 14 | 4,264 | 384,527 | Alaska, Arkansas, Texas, and Washington | 9 | 768 | 57,961 |
| Arkansas, Texas, and Washington | 10 | 2,266 | 204,348 | | 91 | 17,991 | 1,357,781 |

Digitized by Google

*Alaska.*—Arthur J. Skidmore began production of mercury at the Parks Cinnabar mine in the Kuskokwim district in 1938 with an output of 8 flasks. A home-made retort is being used at this property.

*Arizona.*—No production of mercury was reported for Arizona in 1938. At the Ord group work was confined to remodeling the rotary furnace and development underground.

*Arkansas.*—S. E. Evans produced mercury at the Caddo mine in Clark County in 1938. This property and the mine of the Southwestern Quicksilver Co., in Pike County, were the principal producers in Arkansas. The mine of the Mid-Continent Quicksilver Co., also in Pike County, was operated under bankruptcy in 1938, part of the time by a lessee and part of the time by a trustee. Increased activity is expected at this mine in 1939. It is reported that the Big Six Mining Co. plans to build a rotary furnace at its mine in 1939.

Mercury deposits in southwestern Arkansas have been described by Reed and Wells.[5]

*California.*—As usual, California was the principal mercury-producing State in 1938. The production of 12,277 flasks in 1938 was 26 percent larger than in 1937, despite the midyear closing of the Oceanic mine, one of the largest producers in California. The increase was due largely to greater production at the New Idria mine. Contra Costa, Fresno, Inyo, Kern, Kings, Lake, Monterey, Napa, San Benito, San Luis Obispo, Santa Barbara, Santa Clara, Siskiyou, Solano, Sonoma, Trinity, and Yolo Counties contributed to California's output. The New Idria mine in San Benito County, operated by the New Idria Quicksilver Mining Co., was the largest producer. Other large producers were the Mount Diablo mine in Contra Costa County; Sulphur Bank, Mirabel, and Great Western mines in Lake County; Oat Hill mine in Napa County; Klau and Oceanic mines in San Luis Obispo County; New Almaden mine and dumps in Santa Clara County; and Cloverdale mine in Sonoma County.

The Bradley Mining Co. operated its Mount Diablo mine in Contra Costa County throughout the year and made an important production of quicksilver.

The Archer and Mercy mines in Fresno County were operated in 1938. Production at both properties was made in retorts. It was reported that O. R. Rodgers plans to install a concentrating plant at the Mercy mine.

Mercury was produced at the Coso mine, Inyo County, in 1938 by A. W. Legge. A 20-ton Nichols-Herreshoff furnace was installed at this property during the year.

The Walabu Mining Co. produced 31 flasks of mercury at the Cudde, back mine, Kern County, in a Gould rotary furnace.

Bert Harvey produced metal at the Kings mine, Kings County, in 1938.

The principal producers in Lake County were the Sulphur Bank and Great Western mines of the Bradley Mining Co. and the Mirabel mine of the Mirabel Quicksilver Co. Three other properties were producing in 1938. Lake County produced 3,715 flasks of mercury in 1938, the second most important output in California.

Operations were continued for 6 months of the year and mercury was produced at the Franciscan mine, Monterey County, formerly known as the Patriquin mine.

Six properties in Napa County produced mercury in 1938. The principal mine was the Oat Hill, which was active from January 1 to September 1 and recovered 487 flasks of metal in a Gould rotary furnace. The mine was reopened in January 1939. Other producers were the Aetna, Manhattan, Oat Hill Extension, La Joya, and James Creek mines.

The principal mercury-producing mine in the United States, as well as in California, was the New Idria, San Benito County. Two of the four Gould rotary furnaces at the property were operated during the year, treating newly mined ore and material from the old Scott furnace and coarse-ore furnace dumps. About 200,000 tons of dump material averaging about 3½ pounds of mercury to the ton are still available at the mine. Trade reports indicated that 125 men were employed at the property in the final quarter of the year. A labor strike at the mine which lasted 2 months was settled in January 1939. Eight other properties, chief among which was the Aurora, produced mercury in San Benito County in 1938.

San Luis Obispo County produced 1,111 flasks of mercury in 1938. The principal producers were the Oceanic and Klau mines. At the Oceanic mine 11,334 tons of ore were treated in a 75-ton rotary furnace and 597 flasks of metal produced. This mine was closed in midyear, and negotiations for its sale apparently did not result in a change in ownership. The Klau mine was reported to be operating with a skeleton crew at the end of 1938. There were five other producers in the county in 1938.

The Red Rock mine of the Santa Ynez Mercury Corporation, Ltd., in Santa Barbara County, a large producer of mercury in 1937, also produced in 1938, but the company went into receivership in the first half of the year, and the mine was idle thereafter. P. B. de Mandel reported that the Cal-Mer (Lion's Den) mine was closed because reserves of ore were exhausted.

Mercury was produced from newly mined ore and from surface dumps at the New Almaden and Guadalupe mines in Santa Clara County. Metal was also produced at the North Almaden mine.

A new screening concentrating plant with a capacity of 420 to 450 tons a day was completed and put into operation at the Cloverdale mine, Sonoma County, in 1938. Geo. H. Burr, Jr., president and general manager of the producing company, estimated in October that 250,000 tons of 1-percent ore were in sight. After a substantial production the mine was closed late in the year owing to financial difficulties. Trade reports indicated that a new Wyatt furnace was completed and placed in service at the Contact mine in 1938. Five other properties produced mercury in Sonoma County.

*Idaho.*—Press reports indicate that a large deposit of cinnabar ore was discovered recently 16 miles from Weiser and was leased for a 20-year period to L. K. Requa.

*Montana.*—A cinnabar vein is reported in the press to have been discovered by the Western Mines Corporation at its property in Fergus County.

*Nevada.*—Mercury was produced in Esmeralda, Humboldt, Mineral, Nye, and Pershing Counties in 1938, but the total output of the State

Digitized by Google

was only 336 flasks. Considerable prospecting and development work were reported around Fallon and in the Bottle Creek district, Humboldt County. Several properties in Humboldt County produced metal, and press reports claimed that increased production could be expected from this area. Retorts were constructed at two or more mines in Humboldt County during the year, and other retorts were reported to be under construction. Frequent rumors that the Castle Peak mine was about to be optioned to one or another company and reopened failed to result in any production at this Storey County mine. Early in 1939, however, it was reported that the American Quicksilver Corporation had optioned the property and soon would start active operations.

*Oregon.*—Production of quicksilver in Oregon totaled 4,610 flasks in 1938, an increase of 8 percent over 1937. The increase was due mainly to greater activity at the Bonanza mine, Douglas County, where H. C. Wilmot is manager. The recovery of 1,183 flasks of metal from 14,914 tons of ore placed this mine among the leading mercury-producing properties in the country. The other principal producers in Oregon in 1938 were the Horse Heaven mine, Jefferson County, and the Black Butte mine, Lane County. Production was also made in Clackamas, Crook, and Malheur Counties.

Five producing properties in Crook County failed to make a large contribution to the country's total.

The Horse Heaven mine, Jefferson County, was the largest mercury producer in Oregon in 1938 and the second largest in the country. Two other properties in this county produced the metal.

The Quicksilver Syndicate, operating the Black Butte mine, Lane County, treated 19,701 tons of ore in two 75-ton rotary furnaces and recovered 803 flasks of mercury in 1938.

The Opalite mine of the Bradley Mining Co., Malheur County, leased for part of the year, produced in 1938. The furnace building at the mine was destroyed by fire in December 1938.

## FOREIGN TRADE [6]

Imports of mercury for consumption in the United States in 1938 were only 12 percent of the relatively constant rates for 1936 and 1937. Of the 1937 total, more than one-half arrived in the first 4 months. Importations virtually ceased in the closing months of 1937, and this lack of activity was characteristic of most of 1938. Of the 2,362 flasks received, 1,111 flasks were credited to Italy and 1,251 flasks to Spain. Metal known to have been exported from Mexico to this country must have been reexported abroad, because none is credited to Mexico in import statistics. Antimony-mercury concentrates imported from Mexico are treated in this country, and the metal produced therefrom, aggregating more than 2,600 flasks in 1938, is consumed here. Statistics covering this movement are not shown separately in foreign-trade records.

[6] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

| United Kingdom | | | | | 81,760 | 66,801 | 38,788 | 33,046 | | |
| | 774,564 | 481,488 | 593,904 | 381,516 | 1,374,652 | 1,017,817 | 1,437,712 | 1,227,991 | 179,522 | 132,610 |

The threatened invasion by foreign producers of the domestic market for mercury compounds appears to have been unfounded, as importations under this class decreased.

*Mercury compounds imported for consumption in the United States, 1937–38*

| Compound | 1937 | | 1938 | |
|---|---|---|---|---|
| | Pounds | Value | Pounds | Value |
| Chloride (mercuric) (corrosive sublimate) | 35,524 | $16,781 | | |
| Chloride (mercurous) (calomel) | 22,618 | 14,852 | 265 | $358 |
| Mercury preparations (not specifically provided for) | 15,737 | 9,252 | 11,786 | 7,604 |
| Oxide (red precipitate) | 4,405 | 2,740 | 1,011 | 815 |
| Vermilion reds (containing quicksilver) | 52,708 | 49,137 | 33,884 | 30,243 |
| | | 92,762 | | 39,020 |

Exports of mercury totaled 713 flasks valued at $50,184 in 1938 compared with 454 flasks valued at $37,165 in 1937. Of the 1938 total, 160 flasks went to South America, 405 flasks to the United Kingdom, and the remainder in small lots to nearly two dozen countries.

## WORLD PRODUCTION

The following table shows world production of mercury, by countries, from 1934 to 1938.

*Algeria.*—The Societe Nouvelle des Mines de Ras-el-ma has been registered with a capital of 510,000 francs to work the Ras-el-ma quicksilver deposits, the only quicksilver deposits of note in Algeria.

*Canada.*—Nelson P. Meeks, American Vice Consul, reported in midyear of 1938 that although no mercury had been produced on a commercial scale in British Columbia a group of Montreal and Vancouver men were developing a property on Mud Creek in Bridge River Valley. He said that recent press reports indicated that additional deposits of this mineral had been found 15 miles north of the operations on Mud Creek, following erosions and slides that bared the surface of a slab of rock 50 feet wide and many feet deep. The new discovery has lower average values than that at Mud Creek, but tonnage possibilities were believed to exist.

A 10-ton testing furnace began recovery of the metal in the late months of the year.

*Czechoslovakia.*—An article in the Mining World & Engineering Record of February 25, 1939, stated that a French company recently produced about 143,300 pounds of quicksilver in the mines at Mernik and Teplou.

*Italy.*—Italy continued to be the principal world source of mercury in 1938, and output was maintained at virtually the record level of 1937. Production totaled 66,719 flasks in 1938 compared with 66,963 flasks in 1937 and an average of 39,800 flasks for the 10-year period, 1927–36. Demand for Italian metal fell in 1938, however, and exports were only 55,327 flasks compared with 67,075 flasks in 1937. Despite this drop, exports in 1938 were considerably above the 41,357 flasks and 35,851 flasks shipped in 1936 and 1935, respectively, before the civil war in Spain interfered with the normal flow of metal from that source. Stocks of metal in Italy were reported to be low at the end of 1937, but they were substantially increased in 1938 by the excess of production over exports.

*Mercury produced in Italy in 1936, by Provinces*

| Province | Ore mined | | | | | | Metal produced | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|

[1] Lire converted to dollars at the average annual rate of exchange, as published by the U. S. Federal Reserve Board.
[2] Product recovered in the plant of the Società di Monteponi from condensation of mercury vapor obtained in lead smelting.
[3] Exclusive of output at Cagliari.

The most productive deposits in Italy are those of the Month Amiata district in Tuscany, Province of Siena; next in importance are the Government-owned Idria mines, in the foothills of the Julian Alps, Province of Gorizia. According to the Metal Bulletin of November 15, 1938, other producers are the properties of the S. A. Mineraria Argus at Abetina in Tuscany, Province of Siena, and Stabilimento

Digitized by Google

Minerario del Siele, also in Tuscany. The Amalgamated Merchants, Ltd., of London, represents "Mercurio Italiano" and has accounted for about 88 percent of Italian mercury sales. The Argus mine is the principal producer not included in Mercurio Italiano, and the 3,000 to 5,000 flasks ordinarily recovered at this property are sold in the open market.

Of the mercury exported by Italy in 1938, 59 percent went to Germany, 12 percent to Japan, and 6 percent to France. Exports to Germany increased from 24,000 flasks in 1937 to 32,600 in 1938 and those to Japan from 4,000 to 6,600 flasks.

According to Sheridan Talbott, American consul, Leghorn, Italy, workers at the Monte Amiata mine received the following hourly wages in 1938.

*Hourly wage rates at the Monte Amiata mine in 1938, by classes of workers*

| | *Lire* |
|---|---|
| Inside workers: | |
| Miners | 2.354 |
| Assistant miners | 2.259 |
| Laborers, unskilled | 2.165 |
| Outside workers: | |
| Firemen | 1.97 |
| Laborers, unskilled | 1.73 |
| Mechanics, locksmiths, carpenters | 2.14 |

The workday for inside laborers is 7 hours, while that for the remainder is 8 hours. Rates for piecework are 33 percent higher for miners, 31 percent for assistant miners, 35 percent for unskilled laborers working inside the mines, and 30 percent for all others. Overtime rates are 15 percent above normal rates for all categories. The workers are paid for 4 holidays and for a 6-day vacation. Family allowances range from 3.60 lire a week for one child to 6 lire each for four or more children. The family allowances are paid until each child is 14 years old. There is a wage tax of 4 percent on net wages exceeding 180 lire a week, a social-insurance contribution of 2.05 lire a week, and some smaller deductions. The wages noted above were fixed by the collective contract of January 1, 1934, but have been increased in accordance with the decisions promulgated by the Italian Government for all classes of laborers. Furthermore, they were increased 10 percent in 1937 by the company itself. The collective contract was up for renewal in 1938, with prospects for slight wage increases. At the time the consular report was prepared, July 27, 1938, the lire was valued at $0.0526.

*Japan.*—Information covering output and imports of mercury into Japan in 1937 and 1938 is not available. That the situation regarding supplies of quicksilver is serious is attested by the strict control over commercial transactions in this metal announced during the year by the Ministry of Commerce and Industry to the prefectural governors. Reports were current early in the year that there was a brisk demand for mercury for the recovery of gold from poor ores and that mercury was also in demand for the electrolytic reduction of caustic soda.

*Mexico.*—Production of mercury in Mexico increased from 4,936 flasks in 1937 to 8,519 in 1938.

The Bureau of Mines is indebted to Vice Consul Norman L. Christianson for the following summary of operations at the Huitzuco mine.

Digitized by Google

The Huitzuco quicksilver mine, located in north-central Guerrero, is operated at present by Explotadora de Mercurio de Huitzuco, S. A., organized in 1930 and believed to be controlled entirely by Mexican capital. A flotation mill of 160 tons of ore a day capacity is in operation. In the latter part of 1938 the mill was producing daily from 3 to 4 tons of concentrates with an average content of 7 to 11 percent mercury and 25 to 30 percent antimony. The mill was designed by Penhoel-Menardi Engineering Co., Ltd., of Los Angeles. In 1937, 515 flasks of mercury, and from January to March, 1938, 11 flasks of metal were produced experimentally in a Johnson-McKay retort. Refining of concentrates in Mexico has been discontinued, temporarily at least, and all concentrates are now being shipped to the United States for treatment. By shipping the concentrates to the United States advantages are gained in respect to both quicksilver and antimony, for imports of both of these metals are subject to duties, whereas imports of ores and concentrates of quicksilver and antimony are permitted to enter the country duty free. The concentrates are shipped by truck to Iguala, on the Mexico City-Acapulco highway, about 124 miles from the capital and 15 miles from the mine. From Iguala they are sent by rail to Mexico City and thence by rail to Los Angeles, via El Paso, Texas. In 1937, 30,184 short tons of ore, with an average content of 0.315 percent mercury and 1.25 percent antimony, were produced and from January 1 to November 30, 1938, 46,822 tons, containing 0.24 percent mercury and 0.96 percent antimony were produced. Concentrates totaling 552 tons, shipped to the United States in 1937, contained the equivalent of 1,205 flasks of mercury, and those shipped from January 1 to December 19, 1938, contained the equivalent of 2,605 flasks of metal. The reduction of the concentrates has been described by Menardi.[7] Exports of mercury from Mexico for the first 10 months of 1938 totaled 6,908 flasks compared with 4,610 flasks in all of 1937.

*Spain.*—Official statistics covering production and exports of mercury from Spain are not available. However, Roura & Forgas, selling agents for Almaden metal, report that exports totaled 43,424 flasks in 1936, 28,357 in 1937, and 31,060 for 10 months of 1938. Their estimate for all of 1938 was 40,000 flasks. Production during the 3-year period, 1936–38, was below exports, and large quantities of metal were shipped from stocks. There were no stocks of mercury at Spanish ports at the end of 1937 and only small stocks at the Almaden mine.

The Almaden quicksilver industry is discussed at length in Deutsche Bergwerks Zeitung of March 29, 1939, and an abstract of the article appears in the Mining Journal of London.[8]

Information on annual wage rates paid at the Almaden mine in 1938 were reported by American Vice Consul Woodruff Wallner, Valencia, Spain, to be as follows:

[7] Menardi, H. B., Reduction of Livingstonite Concentrate: Am. Inst. Min. and Met. Eng., Metals Technol., vol. 6, No. 2, February 1939, 8 pp.
[8] Mining Journal, London, The Almaden Quicksilver Industry: Apr. 8, 1939, p. 377.

| Drivers of compressors and locomotives, power-station helpers, drivers of mechanical vehicles, and second-class machine-shop men | 4,302.00 | 201.60 | "Buitrones" works: | | |
| Ventilator mechanics | 3,912.50 | 195.62 | Spirek and works foremen | 4,800.00 | 240.00 |
| Smelting mechanics, lime-pit foremen, pit foremen, and timekeepers | 3,780.00 | 189.00 | First-class lime workers and Spirek conveyor-belt foreman | 4,512.00 | 225.60 |
| Oilers, workshop apprentices, errand boys, and messengers | 2,400.00 | 120.00 | Second-class lime workers | 4,032.00 | 201.60 |
| Heating installation and workshop foremen | 4,932.00 | 246.60 | Quicksilver weighers | 4,632.00 | 231.60 |
| Third-class workshop men and scale men | 3,600.00 | 180.00 | Workmen on the quicksilver tubes | 3,900.00 | 195.00 |
| | | | Quicksilver box cleaners | 3,780.00 | 189.00 |
| | | | Master masons | 4,272.00 | 213.60 |
| | | | Master masons' assistants | 3,960.00 | 198.00 |
| | | | Master masons' laborers | 3,600.00 | 180.00 |
| | | | Pit laborers | 3,360.00 | 168.00 |

*United Kingdom.*—Mercury was shipped directly to foreign countries from Spain in 1936, but since the beginning of 1937 all available metal has been exported to London for distribution. As a consequence, figures for imports and reexports of quicksilver for the United Kingdom jumped sharply in 1937 and 1938. Imports were 44,317 flasks in 1938, 49,894 in 1937, and 22,468 in 1936, and reexports during those years were 15,535, 28,127, and 5,571 flasks, respectively. From these data it is evident that the United Kingdom, one of the largest mercury-consuming countries in the world, consumed more metal in 1938 than in 1937. Roura & Forgas, selling agents for the Almaden mine in Spain and Amalgamated Merchants, Ltd., selling agents for most of the Italian metal, have combined offices in London. At the end of 1937 Roura & Forgas were reported to have 22,000 flasks of metal on hand in London. As inventories in Italy and at Spanish ports were low or nonexistent, this metal represented the principal stocks of quicksilver for sale at that time.

| World smelter production | 688 |
| World consumption | 689 |
| Review by countries | 690 |

The prosperous conditions prevailing in the world tin industry during 1937 were sharply reversed in 1938. A substantial decline in demand for tin products in the United States resulting from the industrial recession caused an abrupt curtailment in the consumption of pig tin. This situation was aggravated by the liquidation of stocks of semimanufactured goods (acquired in 1937 in anticipation of price increases), particularly tin plate, production of which declined 40 percent from the all-time high established in 1937, although the demand for tin cans declined only 10 percent, judged from the trend in food packing. Domestic use of tin in solder, babbitt, bronze, and collapsible tubes and foil showed major declines, reflecting the narrower market for automobiles and other consumer goods. Consequently, imports of pig tin, were 44 percent below the record established in 1937. New York prices moved downward during the first part of the year and early in May reached the lowest level since May 1933. Visible stocks of tin in the United States decreased during 1938, and consumers' stocks increased little, if at all; total stocks dropped about 15 percent.

*Salient statistics for tin in the United States, 1925–29 (average) and 1934–38*

| | 1925–29 (average) | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|---|
| Production— | | | | | | |
| From domestic mines, long tons | 24 | 8.2 | 44.5 | 101.0 | 168.4 | [1] 109 |

[1] The long ton is used throughout this report.

Digitized by Google

Outside the United States apparent consumption was approximately 10 percent less in 1938 than in 1937. In contrast to Germany, Japan, and Italy, which took more tin in 1938 than in the previous year, the United Kingdom, France, and the U. S. S. R. took less. Total world visible stocks increased 13 percent and at the end of 1938 were higher than at the end of any year since 1932.

To meet the declining demand, the International Tin Committee made successive reductions in permissible export quotas from 110 percent of standard tonnages in the last quarter of 1937 to 70 percent in the first quarter of 1938, 55 percent in the second quarter, and 35 percent in the last half of the year. World production decreased 30 percent compared with 1937. Countries signatory to the International Tin Control Scheme bore the major part of the reduction, their output having declined 33 percent whereas that of the nonsignatory countries decreased only 10 percent. The latter group produced 19 percent of the total output in 1938 and 15 percent in 1937.

The Buffer Stock Scheme proposed in 1937 was adopted officially in June 1938, and during the latter half of the year an additional production quota of 10 percent was allowed for stock accumulations. The purpose of the pool is said to be stabilization of tin prices between £200 and £230 per long ton (43.5 to 50.0 cents per pound).

*Government action affecting tin.*—The trade agreement with the United Kingdom signed November 17, 1938, bound imports of tin into the United States on the free list provided:

> That the Government of the United States of America reserves the right to withdraw the concession hereby granted if at any time after January 1, 1939, an export tax is charged in Nigeria on tin ore and concentrates exported to the United States of America other than or different from any export tax which may at the same time be charged on tin ore and concentrates exported to any part of the British Empire.

Effective January 1, 1939, the Nigerian Government reduced the export tax on tin-ore shipments to the United States in accordance with this agreement.

The tariff acts since 1922 have provided duties of 4 cents per pound on tin imported into the United States as ore and 6 cents on tin imported as metal whenever domestic production of tin amounted to 1,500 tons per annum. As there was little hope that domestic output would reach that magnitude, the chance of the tariff ever becoming effective has been extremely remote. Thus from the standpoint of the United Kingdom, this concession by the United States has little practical significance. The same may be said of the British concession on Nigerian ore. It has been stated frequently that creation of a smelting industry in the United States, based primarily on the impure tin concentrates produced in Bolivia, would be facilitated if they were mixed with the purer concentrates produced in British and Dutch possessions. Movement of these ores to the United States was precluded in the past by discriminatory export taxes. This obstacle has now been removed as regards Nigeria, and presumably anyone wishing to establish a smelting industry in the United States should be free to compete with the British smelters for clean Nigerian ores. However, in view of the existing commercial relationships between the principal Nigerian producers and the British smelting interests it is believed that despite removal of the discriminating export duty no substantial quantity of ore will be diverted to the United States.

The appropriation bill for the Navy Department for the fiscal year 1938–39 provided $500,000 for the purchase of strategic commodities, most of which was spent for tin. Larger purchases of tin and other strategic commodities are contemplated in legislation now pending in Congress. S. 572, passed by the Senate on March 31, 1939, provides a total of $40,000,000 for this purpose over a period of 4 years and $500,000 annually for 4 years for an investigation of domestic resources of deficient minerals by the Bureau of Mines and the Geological Survey of the United States Department of the Interior. The bill was also passed by the House of Representatives on April 25, 1939, in an amended form providing $100,000,000 for stock-pile purchases. As of May 29, 1939, the conferees had agreed on the provision of $100,000,000 and the bill was awaiting final congressional approval.

H. R. 5840, passed by the House of Representatives on May 1, 1939, proposes to amend the Faddis-Barbour bill licensing the export of tin-plate scrap by including "other scrap, drosses, or residues, the tin content of which is in excess of 10 percentum in which the copper content does not exceed the tin content." Presumably this bill is designed to curtail exports of tin byproducts, such as drosses, which are reported to have increased in recent years. Official quantitative data on this trade are not available.

The McReynolds bill, H. R. 9154 of the Seventy-fifth Congress, was not introduced in the Seventy-sixth Congress. The bill was the outgrowth of the extensive tin investigation conducted by the subcommittee of the House Committee on Foreign Affairs. It provided for the creation of a Board for Strategic Materials to study the supply of tin and other strategic materials in the United States.

The Bureau of Mines conducted concentrating tests on samples of tin ore from Goodwater, Ala.;[2] Majuba Hill, Nev.;[3] and Tinton, S. Dak.[3] Report of Investigations 3404, also published by the Bureau, described the pegmatites at Tinton.[4]

## TIN AND NATIONAL DEFENSE

The present intense interest in national defense has focused attention on strategic materials in which the United States is deficient. Tin ranks high among such materials owing to the essential usefulness of the metal industrially, the lack of commercial deposits, and the almost total dependence of this country on relatively few overseas sources of supply. Under normal conditions the United States consumes more than 75,000 tons of tin annually, or approximately 45 percent of the total world output. Domestic production never has exceeded 170 tons per annum; thus requirements have been met by imported metal. During the past 5 years 81 percent of the foreign purchases was obtained from Asia (69 percent from British Malaya), 18 percent from Europe, and 1 percent elsewhere.

In time of peace this dependence on foreign sources presents no serious problem; adequate supplies usually have been available, and prices seldom have been exorbitant. In the event of war, however,

Digitized by Google

it constitutes a serious threat to national security because foreign sources of supply are vulnerable to blockade by hostile fleets. Deprived of tin, the industrial power and hence the military effectiveness of the United States would be impaired seriously.

During the World War the procurement of deficient strategic materials, including tin, presented many grave problems, and on several occasions severe shortages were averted only by narrow margins. Despite these experiences the United States has done little toward improving its strategic position in tin and at present the problem is more acute than ever, owing to the large increase in consumption since 1918. However, the recent intense interest in national defense arising from the critical international situation has prompted exhaustive consideration of the subject of deficient raw materials by Congress, and as this is written there is every indication that constructive action soon will be taken.

Failure hitherto to adopt constructive measures to end this perilous condition has not been due to lack of proper appreciation of the problem or lack of a simple and sound method for solving it. In 1921 the War Department requested several distinguished tin experts to study the situation. Their report [5] clearly demonstrated the inadequacy of domestic deposits and the hopeless outlook for self-sufficiency in the United States. In 1934 the Planning Committee for Mineral Policy appointed by the President recommended the purchase of a stock pile of tin as the only safe way of guaranteeing adequate supplies in a war emergency. The long delay in facing the realities of the strategic mineral problem may be ascribed primarily to the fact that the American public is not military-minded; therefore there was little incentive for political leaders to stir up interest on this subject among voters whose natural apathy was increased by the prosperity of the twenties and the depression of the thirties. Moreover, a few always have claimed that the tin problem could be solved by proper encouragement of domestic production, by the establishment of a smelting industry based on imported ore, or by the use of substitutes. Obviously the development of domestic industries has a more popular appeal than the purchase of foreign products although, as will be shown, the hope of obtaining national security thereby is indeed remote.

*Domestic resources.*—In a recent (February 28, 1939) study entitled "Report upon Certain Deficient Strategic Minerals," prepared by the staffs of the Geological Survey and the Bureau of Mines, United States Department of the Interior, potential production from domestic tin deposits was summarized as follows:

> *Sources.*—Although tin minerals have been recognized widely in lode deposits in the United States, the principal source of production has been a few placer deposits, largely in a small area in Alaska. Specimens of tin minerals have been found in many places in the United States, but serious efforts to exploit tin-bearing lodes have been confined to the following districts: One in Virginia; two in South Dakota; one in Texas; one in New Mexico; one in California; one in Nevada; and one in Washington. With one exception, that near Temescal, California, each of these districts has been studied by geologists of the Geological Survey, and reports have been issued.
>
> From the nature of the lode and placer deposits of tin, and the manner by which they have been explored, it is impossible to assign definite figures to the reserves of tin. It is safe to state, however, that they are small.

[5] American Institute of Mining and Metallurgical Engineers and the Mining and Metallurgical Society of America, International Control of Minerals: New York, 1925, pp. 115–128.

Digitized by Google

*Production from domestic mines.*—The placer tin deposits near York, Seward Peninsula, Alaska, have been known for about 40 years and have yielded a small output almost every year. The total exceeds that of all other domestic districts combined. From what is known concerning the geology of the region, and the extent of tin-bearing gravels, it is clear that the district presents the best opportunity in the United States to recover the most tin for a given expenditure, although it seems that the maximum yield cannot be more than a small part of domestic needs.

A large sum, at least five million dollars, has been expended in four districts in the United States in attempts to develop lode tin deposits. Probably the largest sum, reported to be more than three million dollars, was spent in the Harney Peak region, South Dakota, from 1884 to 1892, in exploration and mining and milling plants. The campaign yielded only 5,000 tons of crude ore containing 0.25 percent tin, in contrast to expected yields of 1.0 to 1.75 percent. Commonly, several tons of tin ore a year are produced as a byproduct in mining other minerals, but it seems very doubtful that this district contains much material that would yield more than 0.25 percent tin or 5 pounds per ton. The most encouraging area in the Black Hills is probably that near Tinton, where considerable work has been done since 1900 and 14,000 tons from one mine yielded about 0.35 percent or 7 pounds of tin per ton. Here a readily accessible reserve of several hundred thousand tons is estimated to contain from 7 to 12 pounds per ton.

The pegmatites of the Kings Mountain district, North and South Carolina, resemble those of the Black Hills and more than $500,000 has been spent since 1887 in attempts to recover tin from several deposits. The largest shipments from a single deposit (Ross Mine) amount to about 130 tons of concentrate, and the total for the district since 1888 is probably less than 500 tons. Estimates of the probable grade of minable material show a wide range depending largely on the assumed limits of the bodies. It has not been proven yet that bodies containing as much as several hundred thousand tons would yield more than 5 pounds of tin per ton. A detailed study of the district by Federal geologists is in progress.

Tin-bearing veins have been known in the Temescal district, Riverside County, California, since 1853 and nearly one million dollars has been spent since 1868 in three campaigns of exploration. As a result of a recent exhaustive study of the area that cost $20,000, it is revealed that there are probably several hundred outcropping veins, mostly 1 to 2 feet wide, which contain from 0.03 to 0.15 percent tin (0.6 to 3 pounds per ton). The only shoot that has justified mining (Cajalco Mine), produced, in 1890–92, 7,000 tons of crude ore that yielded about 150 tons of tin. When the mine was reopened in 1927–29, at a cost of several hundred thousand dollars, no more ore was found and the plant was dismantled.

Cassiterite was found in the Franklin Mountains, Texas, 15 miles north of El Paso, in 1899. From 1907–1910, four veins were extensively explored, mining, milling, and smelting plants erected at a cost of several hundred thousand dollars, and 8 tons of metallic tin, valued at $6,800, were produced. There is no record of the grade of the crude material, but estimates indicate about 1 percent tin across veins as much as 2 feet wide.

During 1890–92 and 1918–19, considerable work was done at a cost of several hundred thousand dollars on some tin-bearing veins within a 500-acre tract on Irish Creek, Rockbridge County, Va. In digging numerous shallow trenches, open-cuts, and tunnels, several thousand tons of crude ore were recovered, which, on milling, yielded less than 100 tons of concentrate. Federal geologists are now engaged in an examination of the deposits.

In addition to the comprehensive campaigns of exploration summarized above, some exploratory work has been done on tin-bearing deposits near Spokane, Wash.: Lander and Pershing Counties, Nev.; Catron County, N. Mex.; and Coosa County, Ala., but no ore has been shipped. Even though this work yields valuable information, most of which is recorded in official reports, it is not yet demonstrated that these districts are likely to contribute an appreciable production even at very high prices for tin.

The production of tin minerals in the United States and Alaska is not only small but seems to bear little relation to the prices offered for tin. Compared with the prices of other strategic metals, that for tin has fluctuated least during the last 30 years. The price was highest during the War, but if prevailing commodity prices are considered, index prices for tin have been higher in several post-War years. Sufficient information seems to be on hand concerning the tin content of the lode deposits of the United States to say that at the maximum index price of post-War years, no tin ore can be produced from them at a profit. At this price, however, Alaskan placer deposits will probably continue to yield a small production for many years.

Digitized by Google

An estimate of the probable yield of the Alaska placers as well as domestic lodes at higher prices must be largely speculative because many unknown elements enter into consideration. The most dependable information concerning known lode deposits indicates that most of the proven material contains from 0.03 to 0.50 percent tin (0.6 to 10.0 pounds of tin per ton) and that material of higher grade is small in quantity and highly sporadic, both locally and throughout the entire country. The following estimates of production attempt to take into account all that is now recorded concerning the number, distribution, grade of domestic deposits, and the costs that are inherent in existing technique of mining and recovery.

*Potential production of tin in the United States at assumed index prices of $0.50 and $1.00 per pound, in long tons*

| Assumed index price | Potential production | | |
|---|---|---|---|
| | Alaskan placers | Domestic lodes | Total |
| $0.50 per pound: | | | |
| First year | 150–300 | 0–10 | 150–310 |
| Second year | 150–300 | 0–10 | 150–310 |
| Third year | 150–300 | 0–10 | 150–310 |
| $1.00 per pound: | | | |
| First year | 250–500 | 10–50 | 260–550 |
| Second year | 500–1,000 | 200–500 | 700–1,500 |
| Third year | 1,000–2,000 | 500–1,000 | 1,500–3,000 |

It should be emphasized again that many speculative elements enter into these estimates and that they indicate only the order of magnitude of what may be expected.

Unless some unforeseen new major discovery is made it is evident that the United States must continue to rely on foreign sources of tin and that encouragement of domestic production offers little hope of providing national security in tin.

*Domestic smelting industry.*—It has been stated that, from the standpoint of national defense, the establishment of a permanent smelting industry in the United States is advantageous for two reasons. First, it would increase the normal stocks of tin, because the smelters would maintain reserve supplies of ore and finished metal and in addition there would be tin in process of smelting. Second, it would eliminate part of the danger arising from our dependence on foreign smelters, all of which are vulnerable to aerial bombardment. These advantages, however, hardly compare with the security afforded by advance purchase of reserve stock piles as recommended by the President's Committee for Mineral Policy.

Such stocks as would be required to maintain a domestic smelting industry would be relatively small in terms of national requirements. At present, consumer stocks are exceptionally high, yet they are equivalent to only a 3-month supply at a normal rate of consumption. Usually they are adequate for less than 1 month's operation. A smelting industry probably would not add more than an additional 2-month supply, which does not go far in guaranteeing tin requirements for a 2-, 3-, or even 4-year emergency.

Although it is true that smelters could be so situated in the United States as to be relatively safe from aerial attacks they would still have to depend on distant ore-producing centers. Bolivia's peak output in 1929 was equivalent to only 55 percent of the tin consumed in the United States in that year. Assuming that the entire Bolivian produc-

Digitized by Google

tion could be smelted domestically, large tonnages of ore would have to be obtained from oversea sources. Moreover, from a strategic point of view the United States would be worse off dependent on ore imports than on metal imports, as the situation is now. The greater weight of ore compared with metal would aggravate the transportation problem, and since the principal weakness of our present tin position lies in the danger of our lines of communication being cut off, any increase in volume of traffic is undesirable.

During the World War extraordinary conditions developed in the tin trade that made it desirable to smelt Bolivian tin ores in the United States. With resumption of normal conditions after the war, the domestic smelting industry could not compete with foreign smelters and was forced to discontinue operations. The record shows that smelting costs were higher in the United States than in the United Kingdom and Germany, principally on account of higher labor costs.[6] It is therefore evident that if a smelting industry is to be created it can be established only by increasing the cost of tin to American consumers. This cannot be justified on the basis of national defense, owing to the questionable benefits of a domestic smelting industry in time of war.

*Substitutes and restrictions.*—In an emergency during which the tin supply might be cut off the use of tin could be reduced considerably by substitution and restriction, but at a terrific cost in terms of industrial efficiency. The introduction of substitutes always entails delay and confusion and should be avoided as much as possible when industry is being mobilized for war. Peacetime development of substitutes for our deficient raw materials should be encouraged, but their acceptance by industry should be predicated only on the basis of lower costs or better performance. Industry should not be deprived of a metal possessing such useful properties as tin in times of peace merely as a precaution against shortage in a war emergency that can be provided for so simply and so cheaply by accumulation of a reserve stock pile. Large scale substitution for tin in time of war should be considered only as an extreme measure.

*Stock piles favored by Army and Navy.*—For several years the Army and Navy have been advocating stock piles as the logical solution of the national defense problem arising from our deficiency in certain strategic raw materials. The advantages of this method were summarized ably by Capt. F. A. Daubin, United States Navy, Chief, War Procurement Planning Section, office of Chief of Naval Operations, in his testimony before the House of Representatives, Committee on Military Affairs, in March 1939. Captain Daubin stated:

> The importance to the Navy and the national defense of the acquisition of stock piles of these materials may be stated briefly as follows:
>
> The physical possession of adequate reserves of strategic raw materials would afford the United States important advantages, political and military.
>
> As a neutral—it would make us independent of the favors of belligerents who may control the sources of these materials, thereby making simpler the maintenance of neutrality.
>
> As a belligerent—it would insure a ready supply of materials needed by our industrial facilities to produce an uninterrupted supply of munitions so vital at the outset of war when communications are likely to be temporarily disrupted.
>
> Meanwhile, time would be afforded to develop available domestic sources or to find substitutes.

Digitized by Google

It would free us from the necessity of providing ships to transport these materials at a time when ships would be at a premium.
It would free our fleet from the necessity of patrolling the sea lanes involved in such transportation.
It would make ineffective raw material sanctions which may be directed against us by other countries.

The principle of accumulating stock piles as insurance against a war emergency was first accepted officially in the Navy Department appropriation bill for the fiscal year 1938, when $3,500,000 was provided for the purchase of strategic raw materials. An additional $500,000 was appropriated for 1939, and $500,000 is included in the bill for 1940, now pending. The Navy has acquired a small reserve supply of tin and other commodities with this money, but the amount on hand is very small in terms of national requirements.

In an address entitled "Strategic Minerals in the United States," presented at the annual convention of the American Zinc Institute in St. Louis in April 1938, Dr. John W. Finch, Director of the Bureau of Mines, proposed the following two-point program for attacking our deficiency mineral program.

1. The immediate purchase of adequate stock piles of strategic minerals of standard quality as the most effective means of meeting the pressing problems of national defense.
2. The annual appropriation by the Government of $500,000 to be used by the Bureau of Mines and the Geological Survey for the purpose of a comprehensive study of ways and means of adapting our domestic reserves of strategic minerals to a permanent solution of our deficiency mineral problem.

Although there is little hope for tin under point (2), it is gratifying to note that legislation on this subject now pending before Congress, and mentioned in the general summary of this chapter, closely parallels Dr. Finch's constructive program. The funds provided in the various bills are inadequate to supply all the stock-pile requirements, but the impending passage of a bill along these lines indicates that the United States is about to initiate action that eventually may remove the threat to national defense inherent in our dependence on foreign sources of tin and other strategic commodities.

## DOMESTIC PRODUCTION

*Primary tin.*—Mine output of tin in 1938 is estimated at 109 long tons, a decline of 35 percent from the peak of 1937. As usual, Alaska produced virtually all (108 tons) of it; South Dakota contributed only 1 ton.

According to the Geological Survey:

Tin mining in Alaska in 1938 was confined mainly to the placer deposits that have been developed in the extreme western part of Seward Peninsula. Mining in this area has been in progress for a number of years and lately has been decidedly on the increase. In 1938, however, judging from the preliminary reports that have been received, the output of placer tin from this area dropped off somewhat from the high rate established in 1937 but still remained above that of any other year in the entire period during which tin mining has been in progress. Owing to the much lower price that prevailed for tin in 1938, as well as the somewhat smaller quantity produced in that year, the total value of the tin output of Alaska is estimated to have been worth about $100,000 less than in the preceding year.

In South Dakota the Fansteel Mining Corporation operated the Bear Creek mine near Tinton during 1938 and sold a mixed concentrate from which 2,500 pounds of tin ore, containing 1,450 pounds of

Digitized by Google

tin, was obtained. Two other operators reported production of small quantities of tin concentrates from the same region, but apparently the ore was not sold.

*Mine production of tin (content) in the United States, 1910–38, by States*

| Year | Long tons | | | | Value |
|---|---|---|---|---|---|
| | Alaska | South Dakota | Other States [1] | Total | |
| 1910 | 9 | 17 | 10 | 36 | $23,447 |

[1] California, North Carolina, South Carolina, Texas, and Wyoming.
[2] Figures not available.
[3] Less than 0.1 ton.
[4] Subject to revision.

*Secondary tin.*—Production of secondary tin declined 22 percent in 1938 as a result of the decreased consumption of virgin metal. A very large part of the secondary tin produced in the United States is recovered from industrial scrap, and curtailment in tin-manufacturing operations is reflected immediately in secondary production figures. Further details on secondary tin in 1938 are given in the chapter on Secondary Metals (Nonferrous).

*Secondary tin recovered in the United States, 1925–29 (average) and 1934–38* [1]

| Year | Tin recovered at detinning plants | | | Tin recovered from all sources | | | |
|---|---|---|---|---|---|---|---|
| | As metal (long tons) | In chemicals (long tons) | Total (long tons) | As metal (long tons) | In alloys and chemicals (long tons) | Total | |
| | | | | | | Long tons | Value |
| 1925–29 (average) | 900 | 2,000 | 2,900 | 7,500 | 23,100 | 30,600 | $38,034,120 |
| 1934 | 900 | 1,800 | 2,700 | 7,300 | 14,900 | 22,200 | 25,487,600 |
| 1935 | 1,100 | 2,200 | 3,300 | 8,600 | 16,300 | 24,900 | 27,498,200 |

## CONSUMPTION

*Apparent consumption.*—The accompanying table shows the apparent consumption of primary metallic tin in the United States from 1910 to 1938, inclusive. These data do not consider the fluctuations in dealer and consumer stocks, information on which is not always available, consequently they do not reveal precisely the actual trend in consumption. Nevertheless, statistics on apparent consumption are useful in determining long-time trends.

The table shows that apparent consumption reached a peak in 1937 but declined 44 percent in 1938. The figure for 1937, however, exaggerates actual consumption, as there were large accretions to consumers' stocks in that year; 1929 thus stands as the year of maximum tin consumption in the United States.

*Production, imports, exports, and apparent consumption of tin in the United States, 1910–38, in long tons*

| Year | Smelter production | Imports for consumption | Exports (domestic and foreign) | Apparent consumption |
|---|---|---|---|---|
| 1910 | | 46,900 | | 46,900 |
| 1911 | | 47,792 | | 47,792 |
| 1912 | | 51,800 | | 51,800 |

| 1936 | | 76,029 | [1] 386 | 75,643 |
| 1937 | | 88,115 | [1] 313 | 87,802 |
| 1938 | | 49,699 | [1] 205 | 49,494 |

[1] Foreign only, 1931–38; domestic not separately recorded.

*Consumption by uses.*—The following tables show actual consumption of primary and secondary tin by uses, as reported to the Bureau of Mines. Except for tin plate and terneplate figures for 1938 were not available at the time this manuscript was prepared. The data represent the products of the first cycle of manufacture; and, for the purpose of this canvass, any virgin tin emerging from this stage as scrap is considered as secondary metal. The figures thus understate consumption of primary tin, and much of the secondary tin shown duplicates data on the virgin metal because it is metal reclaimed from such byproducts as tin-plate clippings and virgin drosses from tin-plate and tinning mills and other plants consuming virgin tin. In 1937, for example, domestic consumers purchased 82,946 tons of virgin metal, of which 7,523 tons was added to inventories and 75,423

Digitized by Google

tons processed. Of the tin processed 72,928 tons emerged from the first stage of manufacture in the products shown in the accompanying tables; and 2,495 tons was sold as scrap, was lost, or was added to stocks of metal in process.

*Consumption of primary and secondary tin in the United States, 1935–37, in long tons*

[1] Revised figures.
[2] In 1935 pure tin tubing required 940 tons and tin-lined tubing 13 tons; in 1936, 1,476 and 7 tons; in 1937, 1,286 and 10 tons.
[3] Small quantity included under "Miscellaneous."

The principal use of tin is in the manufacture of tin plate. Normally this industry consumes approximately half the virgin tin used in the United States. Production of tin plate declined 40 percent in 1938 compared with 1937. Although the food pack decreased only 10 percent, exports of tin plate fell 55 percent, and can makers drew heavily on inventories purchased before the price rise in 1937.

According to the American Bureau of Metal Statistics, the use of virgin tin in various other products decreased as follows in 1938: Solder, 34 percent; collapsible tubes and foil, 23 percent; babbitt, 38 percent; and bronze, 41 percent.

A new process has been devised for coating copper, brass, and other metallic articles by suspending them in an atmosphere of hydrogen and stannous chloride vapor. The reduced tin alloys with the underlying metal, forming a close bond, and, in the case of copper, a hard tin-copper alloy surface. The process, known as "stannising," is said to be especially adapted to coating objects with an irregular surface, such as screws and bolts.

A. Strauss & Co., Ltd., of London, comments on the growth of substitutes for tin in the United States as follows:

One of the principal uses of tinfoil is the wrapping of cheese. Much of this will be discontinued in the future, and be replaced by a rubberized transparent paper. This substitution, it is stated, will effect a considerable saving in cost. Other changes in industrial processes are resulting in reduced tin consumption. A lead bearing metal, free of tin, is being used in the production of certain automobiles. Substitutes are being increasingly used for tin oxide. The move towards the use of tooth powder instead of tooth paste, brought about by a nation-wide advertising campaign, is diminishing the demand for tooth paste tubes. The increasing popularity of electric shavers is decreasing the sale of shaving cream tubes. Aluminum is now being more freely used in the manufacture of tubes, in view of the high tin price. The tinplate industry still remains, of course, the backbone of tin consumption, but even here new processes are in operation by which the coating of metal has been reduced. An interesting development which may well have some adverse effect on the sale of tinned fruit and vegetables is the new method of refrigeration adopted by the railroad companies. They can now carry to the North throughout the winter fresh vegetables from the South at a figure very slightly above the price of tinned vegetables. The total effect of these developments and substitutions is not serious; they are mentioned as evidence of a tendency.

## FOREIGN TRADE [7]

The principal items in the foreign trade of the United States in tin are imports of pig tin, which supply virtually all the domestic tin requirements, and exports of tin plate. Of minor importance are the import and export trade in tin-plate scrap, exports of tin-plate circles, strips, cobbles, etc., and exports of waste-waste tin plate. There is also an appreciable export of miscellaneous tin manufactures, tin-plated hollow ware, and tin compounds. Virtually all the trivial domestic output of tin ore is exported, and a small quantity of ore is imported annually.

Metallic tin imported for consumption declined 44 percent from the all-time peak established in 1937. Eighty-seven percent of the total imports came from Asia, 12 percent from Europe, and 1 percent elsewhere. Receipts from all major producing areas declined in 1938.

*Foreign trade in miscellaneous tin manufactures and tin compounds, 1934–38*

| Year | Miscellaneous tin manufactures | | Tin compounds (pounds) | |
|---|---|---|---|---|
| | Imports [1] | Exports [2] | Imports | Exports |
| 1934 | $55,525 | $677,266 | 200 | 202,777 |
| 1935 | 57,945 | 776,855 | 22 | 128,632 |
| 1936 | 73,114 | 1,295,484 | 5,959 | 344,578 |
| 1937 | 43,458 | 2,532,747 | 1,715 | 218,006 |
| 1938 | 11,468 | 2,064,504 | 865 | 172,467 |

[1] Tin manufactures n. s. p. f.
[2] Includes tin dross and tin-bearing scrap material other than tin-plate scrap.

The 55-percent decline in exports of tin plate, etc., in 1938 was greater than the decline in foreign consumption, indicating that domestic producers lost ground in the export market. Exports from the United Kingdom and Germany decreased only 29 and 12 percent, respectively.

## PRICES

The average price of Straits tin in New York in 1938 was 22 percent below that of 1937, reacting to the industrial recession that began in the latter half of 1937 and continued into the first half of 1938. The tin quotation at the beginning of 1938 was 41.125 cents per pound. Minor fluctuations occurred during January and February, but toward the last of March a downward trend developed as business continued to lag. The low price for the year—35.00 cents—was recorded on May 2 following a period of uncertainty as to Malaya's position in regard to quota readjustments and buffer pool proposals. Improved deliveries during May, the announcement on June 1 that Malaya would join the buffer pool, and the decision to curtail production further during the third quarter had a pronounced effect on the tin market, and in June and July there was substantial recovery in prices. The following 2 months witnessed little change, but in the closing quarter quotations moved upward with the general improvement in industrial activity. On December 30 the price stood at 46.65 cents; the high for the year was 46.75 cents on December 29.

## STOCKS

Total stocks of virgin tin on hand in the United States at the end of 1938, and metal afloat, decreased 15 percent over 1937. Visible supplies—that is, afloat, at landings, or in licensed warehouses in New York—declined 34 percent during 1938, and stocks at consumers' plants were approximately the same at the beginning and end of the year. The total material on hand December 31, 1938, was equivalent to only a 6.5-month supply at the average rate of consumption in 1938.

World visible supply, exclusive of consumers' stocks, increased 21 percent, as shown in the accompanying table. These data do not include stocks of metal being accumulated by various countries as a reserve against a military emergency. The U. S. S. R. apparently stocked 20,000 to 25,000 tons for this purpose during 1937 and 1938.

Digitized by Google

Recent sharp increases in tin shipments to Japan, Germany, Poland, and Sweden suggest that these countries, also, may be acquiring stock piles. The Navy Department of the United States Government had on hand, as of March 1939, an emergency reserve of 2,190 tons of tin.

[1] Metal Statistics, 1939, pp. 369 and 371. Beginning January 1930, figures for world stocks include carry-over in the Straits Settlements (on lighters and warrants); beginning July 1933, they also include carry-over at Arnhem (Netherlands) smelter.

## WORLD ASPECTS OF TIN INDUSTRY

*International Tin Control Scheme.*—During the first quarter of the year countries signatory to the production-control scheme were operating under quotas representing 70 percent of standard tonnages, a sharp reduction from the 110 percent maintained during most of 1937. This curtailment was necessitated by the drop in demand the last 3 months of 1937. As business continued slack in 1938, production quotas were reduced to 55 percent for the second quarter and to 35 percent for the third and fourth quarters. Standard tonnages of Malaya and Netherland India were increased 7.5 percent effective July 1, 1938. Because this drastic curtailment by signatory countries was not met by the nonsignatory producers, the output of the latter rose to a proportion that would have permitted resignations from the Tin Control Scheme. The original agreement provides that when

Digitized by Google

outside production "has, over a period of 6 consecutive months, exceeded 15 percent of the estimated world production during that period, or 12,500 tons of metallic tin, whichever is the less amount, it shall be competent for any territory to give 6 months' notice of its intention to withdraw from the Scheme." The right provided in the foregoing section was not exercised by any signatory country during 1938. According to E. Baliol Scott,[8] participants in the Buffer Stock Scheme contracted themselves out of this privilege.

The Buffer Stock Scheme proposed in 1937 was formally ratified and put into effect on July 1, 1938. The object of the scheme is to stabilize the price of tin. Limits of £200 and £230 per long ton (43.5 to 50.0 cents per pound with exchange at par, $4.8665) are provided, subject to change by resolution of the International Tin Committee (I. T. C.). The agreement provides for an initial stock of 10,000 tons, which can be increased to a maximum of "approximately 15,000 tons" by resolution of the I. T. C. The stock is to be administered by an executive who is in no way interested personally in the tin industry and who will be guided by general instructions issued from time to time by the I. T. C. In general, the operations of the executive are not to be revealed to any person other than the chairman of the I. T. C., but data on the quantity of tin held and the financial status are to be given to the I. T. C. where tin-control quotas are being considered. The original stock is to be supplied pro rata by members of the tin-control scheme, who likewise will participate pro rata in the proceeds from its sale. The agreement terminates on January 1, 1942.

The draft of the Buffer Pool Scheme was approved by the I. T. C. on March 14, 1938, and submitted to the signatory countries for ratification. Some objection to the scheme was encountered in Malaya, but on May 23 the plan was ratified by Malaya by a 2 to 1 vote. In June the I. T. C. established production quotas for the third quarter at 35 percent for the regular market trade and an additional 10 percent for the creation of the buffer stock. These percentages were reaffirmed for the last quarter of the year. R. G. Mills, a director of the Brazilian Warrant Agency & Finance Co., was appointed manager of the buffer pool in August. Details of the pool's activity during the last half of 1938 were not revealed, but apparently over 10,000 tons were accumulated by the end of the year. On November 22 the I. T. C. voted to increase the buffer stock to 15,000 tons. Production quotas for the first quarter of 1939 were retained at 35 percent for market and 10 percent for stock accumulations.

*World mine production.*—Mine production of tin decreased 30 percent in 1938 compared with 1937. Much of the decline was absorbed by the countries signatory to the International Tin Control Scheme, their output being decreased 33 percent compared with only 10 percent for the nonsignatory countries. British Malaya continued to be the largest producer and contributed 29 percent of the total world output. Bolivia ranked second with 17 percent, Netherland India third with 14 percent, Siam fourth with 9 percent, and China fifth with 8 percent. The output of the unrestricted producers comprised 19 percent of the total production in 1938 compared with 15 percent in 1937 and 11 percent from 1925 to 1929. There were no outstanding new producers in 1938.

*World smelter production.*—As considerable tin enters world trade in the form of ore, geographical data on world smelter output differs materially from those on mine output. For example, all ore from Bolivia and Nigeria is smelted in Europe. An appreciable part of the tin ore from Netherland India is smelted in the Netherlands, and the product of Siam and Indochina is smelted in British Malaya. The only commercial tin ore smelter in the Western Hemisphere is in Argentina, and its output has increased somewhat in recent years.

*World consumption.*—Apparent world consumption of tin in 1938 decreased 24 percent from 1937, according to the International Tin Research and Development Council. This authority states that apparent consumption in the United States declined 41 percent compared with only 10 percent elsewhere. The principal consumers in 1938 and the percentage of the total each consumed were as follows: United States, 33 percent; United Kingdom, 12 percent; U. S. S. R., 11 percent; Germany, 9 percent; Japan, 7 percent; and France, 6 percent. Of these countries Germany and Japan were the only ones to use more tin in 1938 than in 1937. Italy also increased its tin consumption in 1938. The decline in consumption by the U. S. S. R. was due largely to completion of a stock-piling program mentioned elsewhere in this report.

## REVIEW BY COUNTRIES

*Argentina.*—In 1935, it was reported that the Patino, National Lead, and St. Joseph Lead Cos. jointly purchased a 10-year lease on a property in the neighborhood of Rio Rincanada, believed to contain 40,000 tons of tin. A smelter was erected in Buenos Aires. There has been a steady increase in production each year, and in 1938 the output of this property is believed to have reached about 1,700 tons of tin, of which approximately 1,200 tons were smelted in Buenos Aires, and the rest was shipped to Holland for treatment in the form of concentrates.

*Bolivia.*—Owing to the drastic reduction in export quotas in 1938, Bolivia could meet her allotment for the first time since 1933. In 1937 Bolivian exports were 24,373 tons below the permissible total, but in 1938 actual exports exceeded the quota by 3,516 tons. Production has been retarded by the shortage of manpower resulting from the war with Paraguay. Agitation to allot a larger share in exports to the Hochschild group was considered, and on October 4, 1938, a Presidential decree reduced Patino's share for the last quarter of 1938 from 50.34 to 46 percent and increased Hochschild's quota to 26 percent (from 18.8 percent). The decree assigned 5 percent to the Aramayo group, 13 percent to the medium-size producers, and 10 percent to the small miners (defined as those producing less than 60 tons in 1937). However, early in 1939 it was reported that Hochschild's quota was lowered by 5 percent and those of Patino and Aramayo raised 2 percent.

The October 4 action was predicated on the allegation that Patino's reserves are on the decline while Hochschild's reserves and producing capacity are increasing. The annual report of Patino Mines & Enterprises Consolidated, Inc., for 1937, contains the following statement by Patino: "The reduction in our reserves during the last 3 years is caused largely by the insufficiency in the number of workmen available." The proved reserves on December 31, 1937, were 59,291 tons. Patino also states that "Patino Mines and my own companies will always be ready to consider any proposal permitting the establishment of smelters in the United States, providing that the technical and economic difficulties which the project involves can be solved."

Of the 27,886 tons of Bolivian concentrates exported in 1938, 73 percent was treated in England; of the remainder, 26 percent was treated in Germany and Holland. The smelting of tin in Bolivia has been proposed from time to time, and several unsuccessful attempts to do so have been made in the past. These failures have been due to the refractory nature of Bolivian ores and the lack of a cheap fuel supply within the country. More recently, electrolytic methods have been emphasized, and Minerals Yearbook, 1938, called attention to the proposed erection of tin smelters at Oruro, using the Lamy electrolytic process. No further news regarding progress in this venture during 1938 has come to the attention of the Bureau of Mines.

A Supreme Resolution of September 16, 1938, definitely established Bolivia's participation in the Buffer Stock Scheme. The buffer stock formed in June 1934 became ineffective when Bolivia decided in June 1935 to terminate the agreement.

Digitized by Google

*British Malaya.*—During the first half of 1938 British Malaya had an operative standard tonnage of 81,831 tons per annum, consisting of a standard allotment of 71,940 tons and 9,891 tons surrendered by or acquired from other producing countries. As of July 1, 1938, the surrendered and acquired tonnages became inoperative, but British Malaya's standard tonnage was increased 7.5 percent to 77,335 tons.

The 44-percent decline in Malaya's tin output in 1938 caused severe unemployment problems. The number of tin miners decreased from 88,285 at the beginning of 1938 to 57,663 at the end. Most of the idle workers were Chinese who had not returned to China owing to the Sino-Japanese War. To alleviate the situation, the Malayan Government is restricting immigration and accelerating public works to absorb labor on a large scale. It is also financing the production of additional ore above export quotas, which is to be stored and used later in meeting export allowances. Employers likewise are spreading the work to relieve unemployment.

Curtailment in production has been accomplished largely by stopping dredge operations. Normally, dredging is the principal means of ore production, but during several months in 1938 gravel pumping supplied the greater portion of the output. The future of tin mining in Malaya lies in the working of low-grade ground by dredges; and at present about 115 dredges are available. During the summer of 1937 as many as 95 of these were working, and several were being built or were on order. By the end of 1938, however, the number of active dredges had dropped to 55.

Comparatively speaking, Malaya enjoys an enviable position in the tin industry as a low-cost producer. Some operators believe that the production-control scheme has reacted to the detriment of Malayan producers and to the benefit of high-cost producers elsewhere. Sir John Bagnall, of Straits Trading Co., Ltd., for example, has suggested that Malaya would be better off with the greater employment that would result from a larger share in world production at a price of £100 for tin.[9]

For some time Malayan Government land policies have been criticized on the basis that prospecting was being stifled and that in consequence the tin reserve position was threatened. The Mines Department undertook a survey of reserves and issued an estimate of 1,000,000 tons of tin, representing only 10 years' life at the potential producing capacity of 100,000 tons per annum. Sir Lewis Fermor, formerly Director of the Geological Survey of India, was engaged to study the problem and to report to the High Commissioner. Although there were indications that the land restrictions would be eased, no definite action was taken during 1938.

*China.*—In December 1938, A. Strauss & Co., Ltd., reported that—

> The invasion of South China by the Japanese has stopped the exports from the Kwangsi and Kwangtung Provinces, which together amount to about 3,500 tons per annum. The only source of supply is now the Yunnan Province, whose production is approximately 9,000 tons. This metal is shipped via Haiphong. It would therefore appear that the export of about one-quarter of the Chinese tin has been affected by the Japanese invasion.[10]

Digitized by Google

The Chinese tin-mining industry has been described by Ahlfeld in Metal und Erz for May 1938. An abstract in English is given in the London Mining Journal of June 11, 1938, page 566.

*Germany.*—Germany (including Austria) produces little tin; and, despite major efforts to provide substitutes, apparent consumption increased from 9,164 tons in 1936 to 13,474 in 1938. The acquisition of Czechoslovakia increased Germany's dependence on imported tin, as consumption there has averaged over 1,600 tons annually from 1936 to 1938, with little or no local production. In August 1938 it was reported that exploration in the lower levels of the old tin mines near Carlsbad, West Bohemia, disclosed large ore bodies containing about 1 percent tin. Production from this area, adequate for Czechoslovakia's needs, was expected. The ore was to be smelted in Germany. Details on developments since the Munich Agreement are not available.

Germany imported 6,045 tons of tin ore in 1938, of which 5,845 tons came from Bolivia. Imports of metallic tin (crude, scrap, and alloys) totaled 11,900 tons in 1938.

*Italy.*—Italy's tin requirements are supplied largely by imports of metallic tin, which amounted to 4,371 tons in 1938 and were obtained chiefly from British Malaya and neighboring European countries. The small production credited to Italy represents the output of two small mining operations and the tin recovered from scrap.

*Japan.*—Japan produces only a portion of its tin requirements, which have increased rapidly during the past 2 years. Most of the domestic ore has been smelted locally, but the product of some mines has been shipped to Singapore for treatment. To make Japan more self-sufficient in tin domestic production is being stimulated, and a tin property in Siam has been acquired by one of the larger Japanese companies. Smelting facilities are being increased to permit a larger proportion of imports in the form of ore. Recovery of secondary tin and use of substitutes are being encouraged, and distribution of the metal is controlled.

*Netherland India.*—Interest in the proposed merger of the Banka and Billiton operations, mentioned in Minerals Yearbook, 1938, appears to have waned in 1938. According to press reports, one reason for the proposed merger was to place the more aggresive management of Billiton in charge of operations at Banka, where mechanization and the development of low-grade reserves have lagged. In view of this statement the recent acquisition of large dredges by the Banka company is significant. Not only was the Kantoeng dredge, which was lost in the North Sea in 1937 en route to Netherland India, replaced with an even larger unit, but another large dredge was authorized by the Batavian Government. Considerable progress has been made in mechanizing other mining operations, and steam shovels and tractor scrapers are supplanting hand methods to a considerable extent.

In contrast to Banka, the Billiton company has 18 bucket dredges available. The recently completed Karimata dredge was temporarily engaged in dredging for treasure lost with the Lutine, which sank in the North Sea off the harbor of Terschelling at the end of the eighteenth century. When this unit arrives at Billiton, the company will have 14 dredges at this island and 4 at Singkep. Recent increases in capacity by the Banka and Billiton companies may have been

Digitized by Google

inspired in part by a desire to improve the bargaining power of the Netherlanders in anticipation of negotiations for continuance of the present control scheme which expires at the end of 1941.

Although Billiton has more modern production facilities than Banka and can work lower-grade deposits, Banka has a much superior position in regard to grade and quantity of its tin reserves. Costs of production at Banka are thus considerably below those at Billiton.

During 1937 the operative tonnage of Netherland India under the Tin Control Scheme was 41,324 tons, including a standard allotment of 36,330 and 4,994 tons of acquired tonnage and carry-over. The acquired tonnage was surrendered as of July 1, 1938; but, effective the same date, the standard tonnage was increased 7.5 percent to 39,055 tons by the International Tin Committee. Exports of tin (content) amounted to 21,001 tons in 1938, of which 7,208 tons was metal and 13,793 tons was in tin content of ore. All the 18,700 tons of ore exported went to the Netherlands. Banka produced 12,545 tons and Billiton and Singkep 8,456 tons of the total tin exported.

*Netherlands.*—Production of tin at the Arnhem smelter decreased in 1938 from 26,600 to 25,560 tons and ore receipts from 39,600 to 38,200 tons. A substantial decline in ore shipments from Netherland India was partly offset by the larger tonnages from Bolivia and other countries. Of the total ore imports in 1938, 68 percent was derived from Netherland India, 28 percent from Bolivia, and 4 percent elsewhere. Exports of tin decreased from 25,300 tons in 1937 to 24,000 tons in 1938.

*Nigeria.*—The trade agreement signed by the United States and the United Kingdom on November 17, 1938, removes the 5-percent tax on exports of Nigerian tin ores shipped to the United States, effective January 1, 1939. This action is discussed further in the general summary at the beginning of this chapter.

The inability of Nigerian producers to meet their quota allotments in 1937 led to hurried attempts to increase capacity, and much machinery and other plant equipment previously ordered were installed during 1938, although it was not needed to meet the curtailed output for that year.

Total reserves of proved and probable ore, as compiled by the London Mining Journal (Nov. 26, 1938, p. 1092), amounted to approximately 123,000 tons (about 72 percent tin content) of which Associated Tin Mines of Nigeria, Ltd., and London Nigerian Tin Mines, Ltd., controlled 70 percent. Effective January 1, 1938, the managements of these companies were consolidated under Anglo-Oriental Nigeria, Ltd., and during the latter part of the year a complete merger into a new company called Amalgamated Tin Mines of Nigeria, Ltd., was proposed. This group contributed 5,566 of the 7,305 tons of tin exported from Nigeria in 1938. Nigerian concentrates are smelted in the United Kingdom.

*United Kingdom.*—Despite the drastic curtailment in mine production of tin throughout the world in 1938, British smelters increased their output over 9 percent. Imports of ore increased from 51,753 tons in 1937 to 55,553 in 1938. Of the 1938 total, 66 percent came from Bolivia, 20 percent from Nigeria, 9 percent from other British possessions, and 5 percent elsewhere. Receipts from Bolivia increased while those from Nigeria decreased in 1938. The decline in prices

Digitized by Google

during 1938 forced some of the old tin mines in Cornwall to close. A plea was made to the Government for a subsidy to assist the Cornish industry, but it was denied.

*U. S. S. R.*—According to the International Tin Research and Development Council, apparent consumption of tin in the U. S. S. R. increased from an average of 7,600 tons in 1934-36 to 25,125 tons in 1937, then declined to 16,174 tons in 1938. These figures are based on tin shipments from producing countries. The larger shipments during 1937 and 1938 bear out press reports that the U. S. S. R. was accumulating a reserve stock of tin. Imports reported by the U. S. S. R. were 9,664 long tons in 1936, 12,309 tons in 1937, and 7,847 tons in 1938. Comparison of apparent consumption for 1937 and 1938 with previous years and with official Soviet import data indicates that 20,000 to 25,000 tons of tin may have been stocked for emergency use.

## ARSENIC

Production of white arsenic in the United States declined only 1 percent in 1938 as a result of reduced activity at nonferrous smelters where all domestic arsenic is obtained as a byproduct. Imports dropped 26 percent, yet comprised 57 percent of the total apparent consumption, which decreased 28 percent. Although boll-weevil infestation in the Southern cotton fields was severe in 1938, low cotton prices restricted farmers' purchases of calcium arsenate and the financial situation of the railroads curtailed the use of sodium arsenite in weed killing. Lead arsenate requirements of the fruit industry were about normal in 1938. Of outstanding significance in insecticide consumption was the fight waged by Federal and State Governments against outbreaks of grasshoppers and Mormon crickets in the Western Great Plains States and the white-fringed beetle in the South. White arsenic quotations at New York remained at the low price of 3 cents per pound.

*Salient statistics for arsenic in the United States, 1925–29 (average) and 1935–38*

Although complete data on world arsenic production are not available, total output probably declined about 4 percent in 1938. As heretofore, Sweden was the largest world producer. The probable order of importance of other producing countries was as follows: United States, Mexico, France, Germany, Belgium, Australia, and Japan.

## PRODUCTION

Production and sales of white arsenic (arsenious oxide) in the United States in 1938 declined 1 and 25 percent, respectively, compared with 1937. Producers continued to market more of the crude than the refined product.

The three domestic producers in 1938 were American Smelting & Refining Co., Anaconda Copper Mining Co., and United States Smelting, Refining & Mining Co. The first of these placed a plant for the recovery of arsenic-bearing dust in operation at its El Paso (Tex.) smelter. This plant is expected to produce 56 to 60 tons of arsenic monthly.

*Crude and refined white arsenic produced and sold in the United States, 1934–38*

| Year | Crude | | | Refined | | | Total | | |
|---|---|---|---|---|---|---|---|---|---|
| | Production (short tons) | Sales [1] | | Production (short tons) | Sales [1] | | Production (short tons) | Sales [1] | |
| | | Short tons | Value | | Short tons | Value | | Short tons | Value |
| 1934 | 8,997 | 9,030 | $425,680 | 4,099 | 6,593 | $371,598 | 13,096 | 15,623 | $797,278 |
| 1935 | 7,583 | 6,985 | 204,681 | 6,654 | 5,685 | 292,777 | 14,237 | 12,670 | 497,458 |
| 1936 | 9,937 | 8,755 | 266,113 | 5,442 | 6,826 | 352,713 | 15,379 | 15,581 | 618,826 |
| 1937 | 9,936 | 10,903 | 290,733 | 6,878 | 6,733 | 250,822 | 16,814 | 17,636 | 541,555 |
| 1938 | 12,619 | 9,428 | 264,004 | 4,066 | 3,732 | 129,018 | 16,685 | 13,160 | 393,022 |

[1] Includes sales by domestic producers for export.

Average receipts from sales in 1938 were 1.40 cents per pound for crude arsenic and 1.73 cents for refined arsenic, indicating a 5-percent increase from 1937 in the selling value of crude and a 7-percent reduction for refined arsenic.

Of the total sales in 1938, 72 percent was crude and 28 percent refined arsenic. In 1937 only 62 percent of the total sales was crude. All domestic crude arsenic was recovered as a byproduct from the smelting of lead and copper ores. Production, as reported by the Bureau of Mines, is measured after the low-grade flue dusts containing 20 to 30 percent $As_2O_3$ are subjected to a roasting or preliminary refining process. This crude arsenic usually contains 95 to 98 percent $As_2O_3$. Most of the crude arsenic and a small quantity of better-grade arsenic obtained in certain parts of smelter flue systems are marketed without further refining. Some crude arsenic is refined further. Bureau of Mines statistics on refined arsenic include products containing 99 percent or more $As_2O_3$. The arsenic reported as a refined product is not duplicated in the crude arsenic statistics.

## CONSUMPTION

The apparent consumption (sales plus imports minus approximate exports) of white arsenic in the United States in 1938 totaled 25,098

Digitized by Google

short tons compared with 34,692 tons in 1937. Net imports were 48 percent of the 1938 consumption. In addition to white arsenic many other arsenic products were imported for consumption; details are shown in the table of salient statistics at the beginning of this chapter.

The distribution of sales of domestic arsenic in the United States in 1938 was approximately as follows: Insecticides, 47 percent; weed killer, 30; wood preservative, 3; glass manufacture, 2; and miscellaneous, 1. Exports comprised 17 percent of the domestic sales. Most of the white arsenic imported is used by insecticide manufacturers on the Atlantic and Pacific seaboards.

In 1937 production of calcium arsenate totaled 37,001,959 pounds (43,295,354 in 1935) and of lead arsenate 63,291,440 pounds (52,145,851 in 1935).[2] The production and consumption of calcium arsenate usually fluctuate much more than that of lead arsenate. Although consumption of the arsenicals lagged in 1938, use of calcium and lead arsenates in the United States increased approximately 275 and 245 percent, respectively from 1919 to 1936.[3] The use of insecticides has advanced owing to the increased numbers of the older insect species in the United States because of more intensive cultivation and planting and to the advent of new insect pests. The retail cost of all insecticides and fungicides sold in the United States is estimated to exceed $100,000,000 annually, and despite the warfare waged against them, insects and injurious fungi are believed to cause damage approximating $3,000,000,000 annually. Regulations to protect the consuming public require that foodstuffs not only be free from insects but of poisonous insecticidal residues. The latter requirement has stimulated some substitution of organic insecticides less toxic to man for poisonous arsenicals.[4] These new insecticides (rotenone, pyrethrum, etc.) cost more than arsenicals, and their use is not yet extensive from a tonnage standpoint. However, in combating the Mexican bean beetle, magnesium arsenate has largely been replaced by rotenone and deguelin insecticidal constituents derived from roots of the derris vine and cubé plant.

Data are not available on the total domestic consumption of the various arsenic insecticides and fungicides in 1938. The boll-weevil infestation was worse in the Gulf Coast States (Mississippi, Texas, Louisiana, and Alabama) and in Georgia in 1938 than in 1936 and 1937. Estimates (based on manufacturers' production) place calcium arsenate consumption at 45,000,000 pounds in 1936 and about half that quantity in 1937. However, large quantities of calcium arsenate often are purchased by dealers and farmers in anticipation of a serious boll-weevil infestation that does not occur, and this material is not consumed until a succeeding year. It is believed that in 1938 substantial quantities of left-over calcium arsenate were consumed and that farmers could not afford to purchase all necessary requirements because of the prevailing low cotton prices. Calcium arsenate also was used to kill cotton-leaf worms and white-fringed beetles in 1938. Lead arsenate is used regularly to exterminate fruit insects, and consumption in 1938 probably was about that in 1937 (44,000,000 pounds). A large quantity also was used to control Japanese beetles

Digitized by Google

in the Eastern States. Paris green, another arsenical insecticide, was used in truck gardening.

During 1938 the Federal Government purchased and used 1,400,000 gallons of liquid sodium arsenite for grasshopper bait, 297,368 pounds of dry sodium arsenite to destroy Mormon crickets, and 35,000 pounds of calcium arsenate to kill white-fringed beetles. The Department of Agriculture estimates that in 1939 Federal arsenical purchases will exceed 2,100,000 gallons of liquid sodium arsenite, 447,000 pounds of dry sodium arsenite, and 792,000 pounds of calcium arsenate. These insecticides will be used to fight the annual grasshopper and Mormon cricket invasions west of the Mississippi River and to make a more determined stand against white-fringed beetles, newcomers in the Southern States since 1936.

Sheep dips for the extermination of parasites often are made with sodium arsenate, white arsenic, and arsenious sulfide.[5]

The drop in metallic arsenic imports also indicates a decrease in consumption in 1938 owing to the general decline in industrial activity. As in previous years the United States depended on German metal for all of its requirements. Importers of the metal include The Ore & Chemical Corporation, 80 Broad Street, and Pfaltz & Bauer, 305 5th Ave., both of New York, N. Y.; consumers of the metal include the National Lead Co., 111 Broadway, and the American Smelting & Refining Co., 120 Broadway, both of New York, N. Y. Most of the metallic arsenic is used as a metal hardener, as a flux, and in certain alloys. The addition of arsenic to lead-base bearing alloys helps prevent segregation and raises the hardness at both normal and elevated temperatures.[6] Arsenic in copper has a small hardening and strengthening effect, especially in the cold-worked condition, and raises the recrystallization temperature but is virtually without effect on ductility. It decreases the conductivity considerably. It occurs naturally in Lake copper and often is added to electrolytic copper in small amounts.

Arsenical compounds are being used more extensively in medicinal preparations. Among those used in fighting venereal diseases are arsphenamine, neoarsphenamine, sulfarsphenamine, and tryparsamide. The number of doses of arsenicals distributed by State health departments increased from 1,567,348 in the fiscal year 1937 to 2,799,110 in the 1938 fiscal period.

## PRICES

Domestic quotations for white arsenic at New York remained at the low price of 3 cents per pound, carload lots, throughout 1938. Quotations for less than carload lots were 3¾ cents per pound. In recent years white arsenic from foreign sources has enjoyed the benefit of depreciated European currencies and thus has offered considerable competition on both the eastern and western seaboards. The following table shows the slight fluctuations in the price of various arsenical compounds during 1937 and 1938.

*Range of quotations on arsenic and its compounds at New York (or delivered in East) 1937–38* [1]

| | 1937 (cents) | 1938 (cents) |
|---|---|---|
| Arsenic metal, lump, cases, per pound | 42.00–43.00 | 40.00–41.00 |
| White arsenic ($As_2O_3$), domestic, kegs, carlots, do | 3.00 | 3.00 |
| Red arsenic ($As_2S_2$), imported, cases, do | 15.75–16.25 | 15.75–16.50 |
| Calcium arsenate, wholesale, drums, carlots, do | 6.75 | 6.75– 7.25 |
| Lead arsenate, wholesale, drums, carlots, do | 11.50 | 11.00–13.00 |
| Sodium arsenate, wholesale, drums, do | 8.00 | 8.00 |
| Sodium arsenite (liquid), works, drums, per gallon | 30.00–33.00 | 30.00–35.00 |

[1] As reported by Oil, Paint, and Drug Reporter.

The low quotations given in the table often are dealers' prices. Delivered prices for most arsenicals vary in different sections of the United States.

Throughout 1938 the London quoted prices for Mexican (99 percent $As_2O_3$) and Swedish (99.5 percent $As_2O_3$) white arsenic remained at £10 5s. to £10 15s. per long ton and for Cornish arsenic (99 percent $As_2O_3$) at the nominal price of £12 per ton.

## FOREIGN TRADE

White arsenic imports in 1938 declined 26 percent compared with 1937, when imports were the highest ever recorded. Of the 1938 total, Mexico supplied 59, Sweden 20, France 8, Canada 5, Belgium 4, Japan 3, and Germany 1 percent. Imports from Mexico and Sweden decreased 27 and 42 percent, respectively, while those from France and Canada increased 42 and 15 percent, respectively.

Figures on imports of arsenical compounds other than white arsenic appear in the table of salient statistics. Imports of metallic arsenic in 1938 decreased 89 percent compared with those in 1937. Other percentage declines were: Arsenic sulfides 52, arsenic acid 92, calcium arsenate 50, sheep dip 19, paris green and London purple 5, and sodium arsenate 12 percent. All imports of metallic arsenic came from Germany and of calcium arsenate from Japan. Of the 241,602 pounds of arsenic sulfides imported, 144,622 came from Germany, 88,162 from Belgium, and 8,818 from France.

Official export data for white arsenic are not available, but reports of individual domestic producers indicate that about 2,300 tons were sold for export in 1938 compared with 2,200 tons in 1937. Exports of calcium and lead arsenate decreased 3 and 2 percent, respectively. Of the 5,242,882 pounds of calcium arsenate exported, 3,647,700 went to Peru, 1,040,308 to Colombia, 242,470 to Argentina, 75,964 to Mexico, and 65,500 to Chile. Of the 1,021,345 pounds of lead arsenate exported, 279,780 went to Argentina, 262,530 to the Union of South Africa, 122,104 to Chile, 107,561 to New Zealand, 61,716 to Cuba, and 42,280 to Mexico.

## WORLD PRODUCTION

The world output of refined and marketable crude white arsenic in 1938 is estimated at 55,000 metric tons, a decline of 4 percent compared with the 57,000 tons estimated for 1937. The decrease is attributed to the decline in smelter activity in Mexico and a few other countries. A substantial quantity of nonmarketable crude arsenic also is produced annually but is discarded or stored for future refinement. Accurate production data are not available, since some countries fail to record arsenic statistics and others report only on sales or exports. Virtually all the world arsenic output is a byproduct from the treatment of gold, copper, lead, zinc, cobalt, silver, tungsten, and tin ores, and this is greater than demand.

[1] Arsenic is also believed to be produced in Czechoslovakia, Peru, Rumania, Turkey, and the U. S. S. R. Production figures are not available for these countries.
[2] Data not available.
[3] Exports.
[4] Data not available. Estimate included in total.
[5] Arsenic content of ores mined is as follows: 1934, 28,618 tons; 1935, 24,418 tons; 1936, 23,312 tons; and 1937 20,954 tons.

Digitized by Google

*Belgium.*—Arsenic is a byproduct of the lead and zinc smelters of the Société Générale Métallurgique de Hoboken at Hoboken and of the Société Métallurgique d' Overpelt-Lommel at Overpelt. Of the 2,707 metric tons of white arsenic exported in 1938, 1,050 went to the United Kingdom, 632 to the United States, 255 to Argentina, 228 to Germany, 149 to Brazil, and 54 to the Union of South Africa.

*Canada.*—In 1938 Canada exported 1,378,300 pounds of arsenic (not otherwise specified) to the United States. Canada produces a granular variety of white arsenic used by the glass industry.

*France.*—Unconfirmed reports state that metallic arsenic recently began to be produced in France. French imports in 1938 included 18 metric tons of arsenic metal (21 in 1937) and 12 tons of white arsenic (21 in 1937); exports included 0.6 ton of arsenic metal (none in 1937) and 2,910 tons of white arsenic (4,245 in 1937).

*Germany.*—Bigot, Schaerfe & Co. Chemische Fabrik G. m b. H. at Hamburg produces metallic arsenic, much of which is exported. Imports of white arsenic totaled 617 metric tons in 1938 (557 in 1937). Of the 1938 imports, 312 tons came from Sweden, 215 from Belgium, and 89 from France; of the exports (2,845 tons) 514 tons went to Brazil, 335 to Turkey, 298 to the Netherlands, 288 to Denmark, 211 to Belgium, 178 to Spain, 173 to Argentina, and 144 to Hungary.

*Mexico.*—Arsenic and bismuth were among the commodities assessed the additional "export" tax, effective August 9, 1938. A production tax but not the regular export duty also is levied on these commodities. The new additional "export" tax amounts to 12 percent of the value as fixed by the commodity committee; in February 1939 the value placed on arsenic was 0.278 peso and on bismuth 11.343 pesos per gross kilo. The American Metal Co., Ltd., annually exports and distributes substantial quantities of white arsenic in the United States. Of the 8,854 metric tons of arsenic exported from Mexico in 1938 (10,695 in 1937), 8,424 tons went to the United States, 415 to the United Kingdom, and 15 to Germany.

*Sweden.*—Bolidens Gruv A.-B., the largest arsenic producer in the world, is constructing a number of round silos at Rönnskär for the storage of more arsenic. The company maintains a laboratory at Stockholm for research on new uses for arsenic and has achieved some success in the fields of insecticides, timber preservation, and corrosion-resistant concrete. A "Boliden impregnating salt" gradually is displacing imported creosote in Sweden and is used to preserve telephone poles, railroad ties, piles, mine timber, etc.

*United Kingdom.*—Imports of white arsenic totaled 4,359 long tons in 1937—2,211 tons from Sweden, 592 from Belgium, 564 from France, 448 from Mexico, and 100 from the United States.

## BISMUTH

Data on the production of bismuth in the United States are lacking. Consumption probably remained about the same in 1938 as in 1937. As usual, pharmaceutical and alloy manufacturers consumed most of the bismuth. The use of bismuth and arsenical compounds in fighting venereal diseases increased. The price for bismuth metal advanced on April 25, 1938, from $1 to $1.05 in New York and from 4s. to 4s. 3d. per pound in London. In March 1939 the price was increased further to $1.10 and to 4s. 6d. per pound. Bismuth imports increased

Digitized by Google

37 percent in 1938, and unofficial data indicate that exports dropped sharply compared with 1937.

## PRODUCTION

The producers of bismuth in the United States in 1938 were Anaconda Copper Mining Co., American Smelting & Refining Co., and United States Smelting, Refining & Mining Co. Bismuth also is imported and distributed in the United States by the Cerro de Pasco Copper Corporation from its properties in Peru.

## CONSUMPTION

Lack of a complete report on domestic sales and of official data on exports of bismuth prevents accurate appraisal of the annual domestic consumption. Heretofore pharmaceutical and medicinal manufacturers have used about 75 percent and low-melting-point and nonshrinking alloys the rest of the total consumption.

Bismuth subcarbonate, subnitrate, and subgallate are a few of the many bismuth compounds used in indigestion remedies, salves, ointments, powders, and other medicinal preparations. According to the Census of Manufactures the production of bismuth subcarbonate increased from 231,432 pounds valued at $364,265 in 1935 to 247,609 pounds valued at $313,426 in 1937—a 7-percent increase in quantity and a 20-percent decrease in average value. Bismuth subnitrate output declined from 269,193 pounds valued at $360,303 in 1935 to 262,867 pounds valued at $309,678 in 1937—2 percent in quantity and 12 percent in average value. Production of bismuth subgallate increased from 24,328 pounds valued at $38,686 in 1935 to 40,861 pounds valued at $55,270 in 1937—a 68-percent increase in quantity and a 15-percent decrease in average value. Approximately 285,000 pounds of bismuth were consumed in the preparation of these three compounds in 1937. In recent years the consumption of bismuth subsalicylate, bismuth potassium tartrate, and other bismuth compounds for the treatment of venereal diseases has increased. These compounds have largely replaced the mercury compounds formerly used. Bismuth compounds are also employed in preparing patients for X-ray examination, and powdered bismuth is used in X-ray-proof rubber goods.

In the metallurgical field bismuth is used in low-melting-point and nonshrinking alloys of wide practical applications. The metal is employed in almost all low-melting metallic alloys used for fusible plugs, safety devices, dental models, soft solders, and tempering baths for small tools and pieces. The Cerro de Pasco Copper Corporation markets its alloy trade-marked Cerromatrix chiefly for permanent mountings for punch and die parts; Cerrobase, for use mainly as a master pattern metal in the foundry industry; and Cerrobend (Woods metal), for use largely as a filler in bending tubes and moldings. A number of other low-temperature-melting alloys also are available. The principal alloying components used with bismuth are lead, tin, and cadmium. The recently developed free-cutting aluminum alloy, 11S, contains a small percentage of bismuth. Bismuth also is used in small quantities in iron castings, in special brake linings, in enameling and the manufacture of optical glass, in the manufacture of special instruments, and in plastics as bismuth subnitrate.

Digitized by Google

## PRICES

On April 25, 1938, the New York quoted price for bismuth metal was advanced from $1 to $1.05 per pound for ton lots, which was maintained the remainder of the year, according to Engineering and Mining Journal Metal and Mineral Markets. At the same time London quotations increased from 4s. to 4s. 3d. per pound. Late in March 1939, the domestic price was advanced further to $1.10 and the London price to 4s. 6d. per pound. Manufacturers of some bismuth compounds and salts reduced quotations slightly in February, but advanced them substantially in August and October 1938. According to the Oil, Paint, and Drug Reporter, the minimum price for bismuth subcarbonate increased from $1.23 at the beginning of 1938 to $1.53 per pound (fiber drums) at the end of the year, subnitrate from $1.13 to $1.33, and subgallate from $1.33 to $1.58, but the price for subsalicylate remained constant at $2.35 per pound.

## FOREIGN TRADE

Bismuth metal imports in 1938 increased 37 percent over those in 1937. Of the 1938 imports, 91,728 pounds were from Peru and 570 from Canada. Imports of compounds, mixtures, and salts of bismuth decreased 36 percent in 1938. Of the bismuth compounds, etc., imported in 1938, 2,000 pounds were from Germany and 4 from the United Kingdom. In addition bismuth is imported as lead-bismuth alloy and in intermediate metallurgical products, statistical data for which are not available. Imports not valued chiefly for lead in 1938 totaled 779,155 pounds, including 626,830 pounds other than lead. This classification comprised imports from Belgium, the United Kingdom, Peru, and Germany. Of the 49,955 pounds from Peru, only 22,230 were lead; probably the balance was chiefly bismuth.

Official exports of bismuth metal are not recorded, but according to the Oil, Paint, and Drug Reporter shipments from Atlantic and Gulf ports totaled approximately 225,000 pounds in 1938 (about 900,000 in 1937). The bismuth was destined to ports in the United Kingdom and France. These figures doubtless include bismuth of foreign (shipments en route or from bonded warehouse) as well as of domestic origin.

*Bismuth and "compounds, mixtures, and salts of bismuth" imported for consumption in the United States, 1934–38*

| Year | Bismuth | | Compounds, mixtures, and salts of bismuth | |
|---|---|---|---|---|
| | Pounds | Value | Pounds | Value |
| 1934 | 19,327 | $19,927 | 305 | $1,814 |
| 1935 | 102,051 | 78,061 | 871 | 4,798 |
| 1936 | 113,443 | 86,722 | 564 | 4,807 |
| 1937 | 67,225 | 54,007 | 3,145 | 9,117 |
| 1938 | 92,298 | 74,583 | 2,004 | 3,387 |

## WORLD PRODUCTION

World byproduct-bismuth output is estimated at approximately 3,000,000 pounds annually. Europe consumes about 1,500,000 pounds of metal annually, chiefly in pharmaceutical and medicinal prepara-

Digitized by Google

tions. Most of the bismuth distributed in Europe is controlled by the world cartel. To base annual world consumption upon production and foreign trade of the metal is misleading, since the larger bismuth-refining plants seldom are operated until stocks of the metal become low, when metal is exported in large quantities. Consuming countries often import quantities adequate to supply demands for a long period. Likewise, the intermittent operation of bismuth-refining plants also makes it difficult to estimate production by individual years.

Official data on the total world production of bismuth are not available. The principal producing countries, in the probable order of importance, are as follows: United States, Peru, Mexico, Spain, Canada, Germany, and Japan. Virtually the entire world output is obtained as a byproduct in the treatment of lead, copper, silver, gold, tin, and tungsten ores. Most of the production probably is derived from the treatment of lead refinery slime. Byproduct production is greater than demand, and with the present price of bismuth it probably would be uneconomical to extract the metal from other than very high grade bismuth ores.

*North America.*—Mexico produced 409,612 pounds of bismuth in 1938 compared with 312,360 in 1937. Canadian bismuth output in 1938 totaled only 9,516 pounds compared with 5,711 in 1937 and 364,165 in 1936.

*South America.*—The bismuth metal output of Peru totaled 482,382 pounds in 1938 compared with 236,717 in 1937. Peruvian exports in 1938 included 454,657 pounds of refined bismuth in bars (196,132 in 1937) and 49,955 pounds of impure bismuth. The bismuth content of Bolivian exports totaled 42,316 pounds in 1938 compared with 67,942 pounds in 1937. Argentina also produces some bismuth ore.

*Europe.*—Spain doubtless will become an important factor in the world bismuth trade again, now that its civil war is ended. Of the 703,847 pounds of bismuth metal imported by the United Kingdom in 1937, 624,557 pounds were reported from the United States and 75,506 from Canada. Effective February 25, 1939, imports of both bismuth metal and alloy containing more than 50 percent bismuth and 15 percent lead by weight became duty-free. French metallic bismuth imports totaled 160 metric tons in 1938 compared with 40 in 1937. Bismuth is produced in the U. S. S. R. at the Chimkent (Central Russia) and Tetiukhe (Far East) lead works, and near Nerchinsk (Buriat-Mongol Republic) from tungsten-molybdenum ores.

*Africa, Asia, and Australia.*—The Union of South Africa produced 8,800 pounds of bismuth ore in 1938 (370 in 1937), chiefly from Cape Province. Bismuth carbonate occurs associated with tinstone and wolframite in Kigezi, Uganda, and in 1938, 930 pounds were exported.

Despite Sino-Japanese hostilities in South China in 1938, 52,120 pounds of bismuth ore were imported by devious routes into Hong Kong for export. Of the 51,454 pounds of bismuth ore exported from Hong Kong in 1938 (84,911 in 1937), 34,658 pounds went to the United Kingdom, 9,731 to Italy, 4,799 to Australia, and 2,266 to France.

Queensland, New South Wales, and Tasmania produced 20,160 pounds of bismuth ore in 1937.

# MAGNESIUM

By Herbert A. Franke and M. E. Trought

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 705 | Foreign trade | 710 |
| Production | 706 | Technologic developments | 710 |
| Consumption | 707 | World production | 712 |
| Prices | 709 | | |

Increased interest in aircraft in the present national-defense program of the United States has again emphasized the growing importance of magnesium and other light alloys. Production (sales) of primary magnesium in the United States in 1938 was greater than ever before and exceeded that of 1937 by 6 percent. Consumption in industries other than aircraft and munitions probably dropped because of the downward trend in business activity in 1938. Statistics show a 4-percent decline in the use of magnesium structural and nonstructural products. The trend of total domestic consumption cannot be evaluated accurately owing to lack of data on stocks and exports. However, it appears that any decline in domestic consumption in 1938 was more than offset by sales to foreign consumers.

The 10-percent decline in the production of magnesium structural products probably was due to a pronounced drop in the manufacture of portable and high-speed equipment which was offset only partly by larger consumption in the aircraft industry. Considerable magnesium is used annually as a deoxidizer in the metallurgical industry and as a component of aluminum and other alloys, but the quantity so used probably decreased in 1938. The quoted nominal price of magnesium at New York remained unchanged at 30 cents per pound throughout 1938 but was reduced to 28 cents per pound in March 1939.

Outside of the United States production of magnesium increased at an even more rapid rate. World output totaled possibly 22,000 metric tons, an increase of 22 percent over that indicated for 1937. Germany continued as the outstanding producer, with an estimated output of 12,000 tons. Consumption also has advanced more rapidly in Germany, the United Kingdom, and other European countries than in the United States, particularly with regard to structural products used in airplanes, automobiles, and other transportation facilities. The rapid growth in the use of magnesium abroad is due to the armament and self-sufficiency programs of totalitarian and democratic countries as well as to development of new uses based upon its lightness and strength.

Digitized by Google

## PRODUCTION

Sales of primary magnesium in the United States in 1938 totaled 2,410 short tons and thus established a new record. The Dow Chemical Co. of Midland, Mich., supplied the entire output. As heretofore the metal was produced by the electrolysis of magnesium chloride derived from undergound brine.

Because magnesium is classed as an essential material by the Army and Navy Munitions Board and because interest in national defense is high, the accompanying historical table is presented, which shows the quantity of domestic magnesium sold or used since 1915, when the industry was inaugurated. Prior to that time metallic magnesium was imported from Germany. The number of domestic producers dropped from five during the World War to two in 1920. In 1927 the American Magnesium Corporation ceased producing primary ingot, and since then the Dow Chemical Co. has been the sole producer and has supplied virtually all domestic requirements. Imports have been of little consequence since 1922. Exports of magnesium have been relatively large since 1933, but official data thereon are not available.

*Magnesium sold or used by producers and imported into the United States, 1915–38*

| Year | Sold or used by producers [1] | | Imports for consumption [2] | |
|---|---|---|---|---|
| | Pounds | Value | Pounds | Value |
| 1915 | 87,500 | $440,000 | (3) | (3) |
| 1916 | 75,400 | 311,462 | (3) | (3) |
| 1917 | 115,813 | 233,626 | (3) | (3) |
| 1918 | 284,118 | 615,217 | [3] 11,899 | [3] $16,259 |
| 1919 | 127,465 | 247,302 | 13,239 | 13,583 |
| 1920 | 123,800 | 233,200 | 29,275 | 25,055 |

## CONSUMPTION

Lack of complete and official data on stocks and exports of magnesium prevents an accurate appraisal of annual domestic consumption. However, the substantial increase in exports indicated by unofficial data compared with the moderate increase in sales, the general recession in business conditions, and the falling off in production of manufactured magnesium products suggest that domestic consumption decreased in 1938.

Of outstanding interest in recent years is the trend in consumption of magnesium-rich alloys used as structural materials. Their use increased nearly 500 percent from 1932 to 1938, inclusive, despite a slight decrease in 1938. The 10-percent drop in consumption of structural products in 1938 compared with 1937 is ascribed to lower activity in the portable and high-speed equipment industries. The

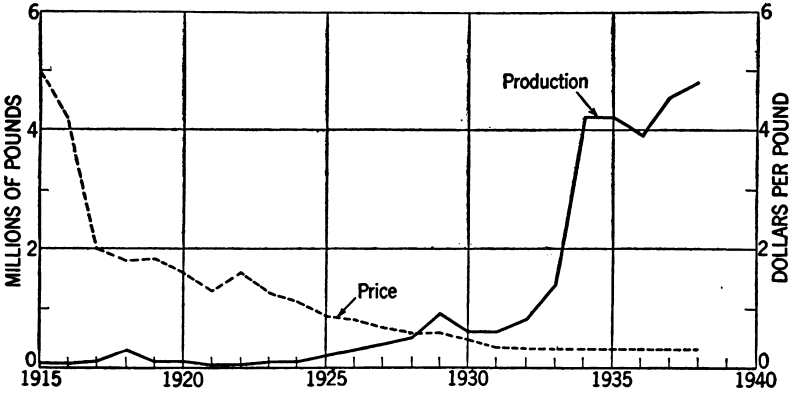

FIGURE 1.—Trends in quoted price and production of magnesium in the United States, 1915-38.

use of magnesium structural products in aircraft gained, and in 1939 and 1940 consumption in this industry is destined to be the greatest in history. The advance in consumption of nonstructural products in 1938 is attributable partly to the increased manufacture of pyrotechnics. The use of magnesium as a scavenger and deoxidizer in the metallurgical industry and as a component in aluminum and other alloys probably declined in 1938.

The following table shows the magnesium sold or used by domestic fabricators of magnesium metal and magnesium-rich alloys. Total manufactures of structural and nonstructural products decreased 4 percent from 1937 to 1938, and production of alloy ingot dropped 40 percent. Of the structural products, sales of sheet gained 6 percent, while sales of castings declined 10 percent, sales of structural shapes, rods, and tubing 8 percent, and those of forgings 81 percent. The 83-percent increase in the manufacture of total nonstructural products in 1938 is slightly exaggerated, as some products classified as "Wire and ribbon" were included under "Structural shapes, rods, and tubing" in 1937. Sales of ribbon decreased slightly.

The value of magnesium castings averaged $1.31 per pound in 1938 compared with $1.17 in 1937.

## A list of magnesium fabricators in the United States in 1938 follows:

Louis Allis Co., 427 East Stewart Street, Milwaukee, Wis.
American Foundry Equipment Co., 400 South Byrkit Street, Mishawaka, Ind.
American Magnesium Corporation, Gulf Building, Pittsburgh, Pa. (Plant at 2210 Harvard Avenue, Cleveland, Ohio.)
Bohn Aluminum & Brass Corporation, 1400 Lafayette Building, Detroit, Mich. (Plant at 3516 Hart Avenue, Detroit, Mich.)
Detroit Pattern Plate Co., 6304 Epworth Boulevard, Detroit, Mich.
Delco Products Division of General Motors Corporation, 329 East First Street, Dayton, Ohio.
Doehler Die Casting Co., 386 Fourth Avenue, New York, N. Y. (Plant at Batavia, N. Y.)
Dow Chemical Co., Midland, Mich.
Eclipse Aviation, Division of Bendix Aviation Corporation, 1265 McBride Avenue, Little Falls, N. J. (Plant at West Paterson, N. J.)
Fremont Flask Co., Fremont, Ohio.
H. L. Harvill, Inc., 2344 East 38th Street, Los Angeles, Calif.
Hills-McCanna Co.,[1] 2353 Nelson Avenue, Chicago, Ill.
Hoover Co., North Canton, Ohio.
Madison-Kipp Corporation, Madison, Wis.
Magnesium Fabricators (Division of Bohn Aluminum & Brass Corporation), East Maumee Street, Adrian, Mich.
Magnesium Products, Inc.,[1] Los Angeles, Calif.
Pyle Pattern & Manufacturing Co., 1137 Sanford Street, Muskegon Heights, Mich.
Reliance Electric & Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio.
Springfield Bronze & Aluminum Co., Springfield, Mass.
Wellman Bronze & Aluminum Co., 6017 Superior Avenue, Cleveland, Ohio.

[1] Commenced fabrication in 1939.

Digitized by Google

Westinghouse Electric & Manufacturing Co., Cable Avenue, East Pittsburgh, Pa.
Wright Aeronautical Corporation, 132 Beckwith Avenue, Paterson, N. J.

New fabricators in 1938 were Fremont Flask Co., Madison-Kipp Corporation, and Magnesium Fabricators. The latter manufactures Magalloy X alloys (formerly trade-marked Bohnalite X). The alloys manufactured by the Dow Chemical Co. are trade-marked Dowmetal and those of the American Magnesium Corporation are known as AM Alloys.

The aircraft industry continued to increase its consumption of magnesium alloys in 1938, particularly sand and die castings. In airplane engines, magnesium castings were employed for crankcases, blower sections, accessory housings, pump bodies, rear sections, diffuser plates, and many miscellaneous parts. In the fuselage the metal was employed in landing and tail wheels, cockpit fittings, pedals, doorframes, levers, housings, and other secondary structural parts and interior appointments.[2] Sand castings weighing more than 300 pounds are used in some airplanes. The use of magnesium in aircraft is receiving more attention because the saving in weight means increased pay load, reduced power consumption, and improved performance. Experimental applications of sheet and shapes for cowling, fairings, and other secondary parts of planes are said to be successful. The aircraft defense program of the United States, the large foreign orders for airplanes, and the increased application of lighter structural parts are expected to increase magnesium consumption significantly in 1939 and 1940.

Magnesium structural products also are employed in portable tools, packaging machinery, vacuum cleaners, portable typewriters, optical instruments, small sewing machines, electric-motor fans, cameras, textile equipment, foundry flasks, and many other articles of portable and high-speed equipment. The textile field offers many opportunities for the use of magnesium products.

## PRICES

The nominal New York price for 99.8-percent ingot magnesium remained unchanged at 30 cents per pound, carload lots, throughout 1938, according to the Engineering and Mining Journal Metal and Mineral Markets. Quotations for less than carload lots, 100 pounds or more, were 32 cents per pound, with a premium of 5 cents a pound over ingot price for specified stick sizes (¼, ⅜, ½, 1, and 2 pounds each). Late in March 1939 the domestic price was reduced 2 cents, to 28 cents per pound for ingots in carload lots and to 30 cents per pound for 100-pound lots or more. The four-notched ingots commonly furnished are 4 by 4 by 28 inches and weigh approximately 17 pounds. Alloy ingot normally is quoted at 3 cents per pound more than pure magnesium ingot.

London quotations for magnesium in 1938 ranged from 1s. 5d. to 1s. 6d. per pound for ingot and stick and from 2s. 9d. to 5s. 6d. per pound for powder, according to grade and specification.

## FOREIGN TRADE[3]

Although official export data on magnesium are not separately recorded, published information [4] indicates that a substantial quantity of the magnesium produced in the United States in 1938 went to Japan, the United Kingdom, and other European countries. Magnesium imported in 1938 comprised only 60 pounds of sheets, tubing, ribbons, etc., valued at $188. Imports in 1937 were 1,321 pounds of powder valued at $1,727. Of the 1938 imports, 48 pounds were from the United Kingdom and 12 from Germany.

## TECHNOLOGIC DEVELOPMENTS

Perhaps the greatest development during 1938 was the method devised to protect magnesium alloys from corrosion. The Dow Chemical Co. announced a caustic (sodium hydroxide) pressure treatment that produces a dense, adherent, abrasion- and corrosion-resistant film on the metal surface. The coating was designed primarily for the decorative treatment of small parts, such as die castings, as the film may be dyed a wide variety of colors as it is being formed. Its resistance to salt-water corrosion is said to be good. A process developed for the treatment of sand castings is claimed to afford protection superior to that of any other known method. It consists of a hydrofluoric acid dip followed by immersion in a boiling water solution of sodium dichromate. Another treatment for sand castings has been approved by the Navy Bureau of Aeronautics as an alternate for the PT–13 anodizing process. It includes surface cleaning, a dip in hydrofluoric acid followed by a boil in a solution of ammonium sulfate and sodium dichromate, and a seal by boiling in an aqueous solution of arsenous oxide. Paint is used as a final step in all methods of protecting the surface of magnesium alloys. A zinc chromate primer meeting Navy specification P–27 provides maximum protection and exhibits satisfactory adhesive qualities.[5] Navy specification and proprietary finishes based on glyceryl phthalate and phenol-formaldehyde resins give good results outdoors and in corrosive atmospheres, and lacquer type materials are satisfactory indoors. Research is being conducted on the reduction of iron and copper impurities in magnesium alloy to improve corrosion resistance. All these developments are expected to advance the use of magnesium alloy in saline, humid, and heavy industrial atmospheres.

The protective-treatment process for magnesium alloys invented by Sutton, Le Brocq, and Savage (British Patent 493,935) also is receiving wide recognition. The metal is treated by electrolysis in a solution of chromic acid and various other salts.

High-strength alloys for extrusions and forgings were studied intensively during 1938. A material has been produced experimentally, which has an ultimate strength exceeding 60,000 pounds per square inch and a yield strength of 50,000 pounds per square inch. As a result of development work in the forging field, magnesium alloys can be hot-pressed into more intricate shapes and larger pieces than

[3] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

before. Research also has produced new casting and extrusion alloys with higher mechanical properties and corrosion resistance. A new die-casting alloy, Dowmetal R, is characterized by increased toughness and improved castability compared with Dowmetal K. It consists of 8.5 to 9.5 percent aluminum, 0.13 percent manganese, 0.4 to 0.8 percent zinc, and the remainder magnesium. Considerable research is being done in the United States and the United Kingdom [6] on the addition of silver to magnesium alloy. The results indicate a combination of high-yield strength with good ductility and no loss of corrosion resistance.

Low-grade magnesite ore can be concentrated by flotation methods developed by the Metallurgical Division of the Bureau of Mines.[7] The metal can be produced from concentrates either by the electrolysis of $MgCl_2$ obtained by chlorination or by reducing the calcined concentrates with carbon in an electric arc furnace at a temperature of about 2,000° C. In the latter process, originally developed in Austria, the metallic vapor formed is chilled suddenly as it leaves the furnace, and the condensate (consisting of metal powder, oxide, soot, and other impurities) is separated from the gaseous products. The metal is distilled from this product in a second furnace. The Bureau of Mines has made a substantial contribution to the solution of some of the unusual and difficult problems involved in this process.

The Northwest Magnesite Co. completed construction of a 5-ton (daily) experimental plant at Chewelah, Wash., in the fall of 1938 for the beneficiation of waste magnesite ores by flotation. This work suggests the possible future utilization of magnesite for the production of magnesium with cheap power generated at Bonneville and Grand Coulee.

The use of sea water and bittern as a source of magnesia for metal manufacture in the United States was recently suggested.[8]

The occurrence, production, and properties of magnesium are given in a recent German publication.[9] British magnesium foundry practice includes the addition of bentonite and iron oxide to the silica sand mold.[10] Surface rolling has been found effective in improving the fatigue strength of magnesium-alloy parts (e. g., aircraft propellers) which are subjective to erosion action.[11] Numerous United States patents have been granted recently in connection with magnesium production processes (Nos. 2,144,339, 2,134,969, 2,132,408, 2,123,990, 2,122,435, 2,147,645, 2,148,358, and 2,111,661), treatment methods, alloys, etc. British Patents 465,097 and 487,836 describe the thermal reduction of dolomite to magnesium using silicon or ferrosilicon and a small quantity of cryolite or other fluoride. Powdered magnesium can be used in the form of porous compacts for pyrotechnics.[12]

## WORLD PRODUCTION

Despite the continued increase in consumption of magnesium in recent years, official data on world production are still lacking owing to the fact that only estimates are available for all countries except the United States. It is estimated that the world produced 22,000 metric tons of magnesium in 1938 compared with 18,000 tons in 1937. The 1938 estimate by individual countries in tons is as follows: Greater Germany, 12,000; United Kingdom, 2,200; United States (sales), 2,186; Japan, 2,000; France, 1,800; Switzerland, 800; U. S. S. R., 600; and Italy, 400. The magnesium chloride electrolytic process continued to supply the greater part of the output. The principal raw materials used were potash final liquor, carnallite, magnesite, and brine. It is expected that a larger part of the output will be furnished by the thermal reduction process in 1939 when new plants in the United Kingdom, Japan, and Italy are scheduled to begin production. These new plants will use magnesite and dolomite as raw material. Since 1934 the number of producing countries has doubled, and the number of metal reduction plants has increased from 7 to 17. Before the end of 1939 probably more than five additional plants will be in operation.

*Canada.*—Reports state that the production of magnesium is contemplated in British Columbia and Quebec. The Consolidated Mining & Smelting Co. of Canada, Ltd., is conducting research on an electrothermic magnesium process.

*France.*—The production of magnesium is estimated at 1,800 metric tons in 1938 compared with about 1,500 tons in 1937. Although the three producing plants now use imported magnesite, dolomite could be utilized by making a few changes in the process. The reduction plant at Jarrie (Isère) was expanded considerably in 1938. During 1938 French imports of magnesium and its alloys totaled 159 tons (67 tons in 1937).

*Germany.*—Despite the set-back of the German magnesium industry in 1937 due to decreased exports, output in 1938 is estimated at 12,000 metric tons. At the end of 1937 about 6,000 tons of metal were in stock, but it was expected that domestic consumption would gain 5,000 to 6,000 tons in 1938 owing to measures taken to replace imported metals with magnesium. The automobile industry increased its consumption of magnesium alloys from 170 tons in 1936 to 1,400 in 1938, or 724 percent, by replacing aluminum and tin structural parts. This industry is expected to consume 2,500 tons of magnesium alloy annually in the near future. Magnesium alloys are employed in street cars and in place of copper-zinc alloys in the manufacture of engraving plates. The metal is also used for bus bars, switch installations in telephone apparatus, optical parts, measuring instruments, and similar equipment. The highly destructive German-made aerial bomb used in Spanish Civil War raids on Barcelona consisted of ammonium nitrate, powdered charcoal, and aluminum, enclosed in a magnesium-alloy shell. Germany has adequate magnesium-fabrication facilities, as only 40 percent of the foundry and 20 to 30 percent of the milling capacity was utilized in 1937.

The I. G. Farbenindustrie A. G., Bitterfeld, the leading producer, is supplementing potash end-liquor raw material with increasing quantities of Austrian magnesite. The metal is derived from the electrolysis of magnesium chloride at a temperature of 700° C. The Wintershall A. G., Heringen, on the Werra River uses carnallite as

Digitized by Google

raw material and produces about 1,000 tons of metal annually by electrolysis. The former cost of producing magnesium ingot in Germany (1,835 RM. per metric ton) is believed to have been reduced in 1938. The Austrian Magnesite Co. and Steirische Magnesit A. G. are constructing a new 200-ton capacity (annual) magnesium plant at Radenthein in Kärnten, Austria. These companies own extensive and high-grade magnesite reserves in the Veitsch Valley, Steiermark, Austria, which have added materially to Germany's already adequate raw-material sources for magnesium.

Data upon magnesium exports in 1938 are not available, but they are believed to have been considerably less than in 1936, when approximately 3,400 tons were shipped to the United Kingdom, Czechoslovakia, and Italy.

*Italy.*—Magnesium is produced by the Società Anonima Magnesio Italiano Sulcis near St. Giovanni, Sardinia, by the electrolysis of magnesium chloride derived from domestic dolomite. Both Società Anonima per il Magnesio e le Leghe di Magnesio and Montecatini are constructing magnesium plants at Bolzano, which expect to begin operations in 1939. Apparently the former concern will reduce dolomite in an electric furnace in the presence of an iron catalyst and then condense the magnesium vapor by a special process.

*Japan.*—Although the production of magnesium in Japan has advanced greatly, published information indicates that it was necessary to import about 600 metric tons of metal from the United States alone in 1938 to supply demands. The Japanese output of magnesium in 1938 is estimated at 2,000 tons. Companies producing metal included the Nichiman Magnesium Co., Ltd., the Japan Magnesium Metal Co., Ltd., the Asahi Electro-Chemical Industry Co., Ltd., and the Japan Soda Co., Ltd. The first concern plans to increase its capacity from 900 to 1,500 tons of magnesium annually, which will make the total capacity of the four companies 4,220 tons. Both magnesite and sea water are used as raw materials, and both the thermal reduction and magnesium chloride electrolytic processes are employed. Metal production is planned by the Kwanto Electro-Chemical Co., Chosen Riken Metals Co., Japan Magnesium Co., Shinetsu Nitrogen Co., Manchurian Magnesium Manufacturing Co., Oriental Metal Industrial Co., and others. The Manchurian Magnesium Manufacturing Co. plans to build a plant in Yingkow and to use magnesite from Tashihchiao and magnesium chloride from salt works on the Gulf of Liaotung. The nationalization of the electrical industry in Japan is expected to result in the extension and consolidation of magnesium-producing companies and entrance into the field by power and aluminum companies.

*United Kingdom.*—British magnesium output in 1938 is estimated at 2,200 metric tons, although one source reports the output as 7,000 tons. The two British magnesium producers, Magnesium Elektron, Ltd., Clifton Junction,[13] and Magnesium Metal & Alloys, Ltd., Rainham, Essex, extended the productive capacity of their plants in 1938. Magnesium Elektron, Ltd., planned to utilize British dolomite instead of imported magnesite by the end of 1938.[14] The other concern is continuing development work on its thermal reduction process employing calcium carbide as the reducing agent. The new plant

Digitized by Google

of the Magnesium Metal Corporation at Port Tennant, Swansea, England, was scheduled to begin production early in 1939. The Lancashire Metal Subliming Corporation, which is erecting a new magnesium works at St. Helens, Lancashire, reported the satisfactory operation of its pilot plant. Early in 1939 the International Alloys, Ltd., announced construction of another magnesium plant, near Cardiff, South Wales, to be operated by the Cardiff Corporation. As a result of the armament program there was a considerable expansion in magnesium fabrication facilities in the United Kingdom in 1938.

British imports of magnesium and its alloys in 1938 totaled 1,637 metric tons compared with 2,265 tons in 1937. Of the 1938 imports, 1,362 tons were from Germany, 208 from the United States, 46 from France, and 21 from Switzerland. The decline in imports indicates the effect of the growing domestic output of magnesium. Only 16 tons of metal were exported in 1938.

*Yugoslavia.*—A Yugoslav firm is experimenting with the production of magnesium metal from magnesite, large deposits of which occur near Maglaj, Uzice, and Vucitru and along the Vardar River.

## ANTIMONY

The world antimony market in 1938 was influenced mainly by two factors—the slump in industrial activity in the United States and the curtailment of supplies from China. The net effect on prices was a substantial recession from the unusually high levels of 1937.

In the United States apparent consumption dropped 36 percent; but the decrease in actual consumption was less severe, as producers' and consumers' stocks were reduced during the year. Production of antimony contained in antimony ores fell 49 percent and supplied less than 6 percent of the total apparent consumption. Imports comprised only 59 percent of the quantity received in 1937; 84 percent of the antimony imported in 1938 was in the form of ore. Mexico continued to be the chief source of supply, but Bolivia increased in relative importance at the expense of Mexico. Imports of regulus totaled only 821 short tons and were the lowest in over 50 years.

Quotations for Chinese metal during 1938 trended downward despite the threatened shortage of supply, and published prices apparently were nominal for most of the year. Quotations for American metal remained more or less independent of those for Chinese metal, the average for the year being 12.35 cents per pound compared with 15.35 cents in 1937. Heretofore, American brands usually were priced 0.25 to 0.50 cent below Chinese brands, but in 1938 the differential averaged 2.24 cents. The quotation for Chinese 99-percent metal averaged 14.59 cents in 1938 and 15.30 cents in 1937.

Ore supply to the smelter at Laredo, Tex., was adequate throughout 1938, although the plant was shut down from April 25 to September 24. Finished products on hand were ample to meet customers' reduced requirements at all times. Antimony oxide was in greater demand than the metal during 1938. A new source of antimony

[1] Figures on imports and exports (except as otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

metal in the United States is the Los Angeles plant of the Menardi Metals Co., which began to produce antimony in 1938. The plant treats a mixed mercury-antimony concentrate imported from Mexico. The American Smelting & Refining Co. is said to be considering antimony production at its Perth Amboy plant, but no output was reported for 1938.

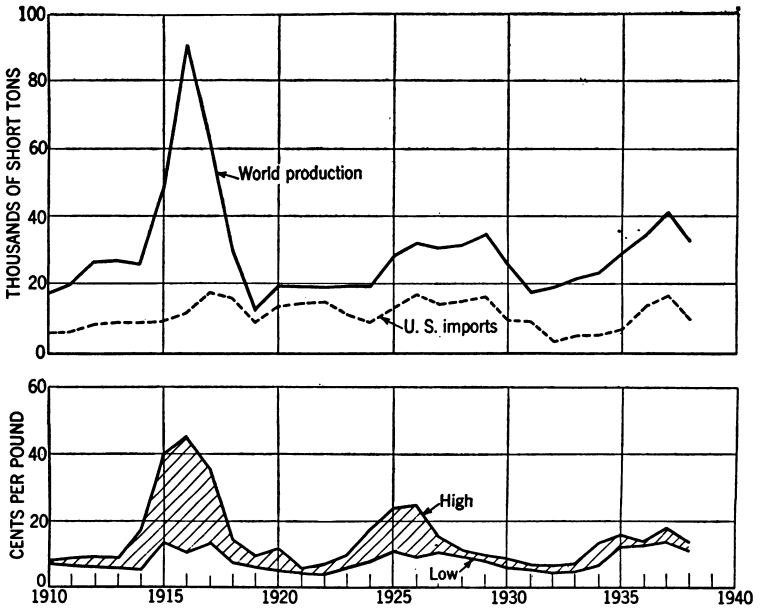

FIGURE 1.—Trends in world production, United States imports, and New York price of antimony, 1910-38.

World production was about 20 percent lower in 1938 than in 1937 (see fig. 1). Production in China (exports) declined 47 percent, whereas output in Bolivia, also measured by exports, increased 32 percent and was the highest on record. Bolivia thus attained first rank in antimony production in 1938. Mexico produced 24 percent less and fell from second to third place in world output.

Throughout the year lines of communication between the antimony-producing centers and exporting points in China were harassed by Japanese activities in South China; and after the fall of Canton in October 1938 shipments from the mines virtually ceased, although exports from stocks at Hong Kong continued. Total exports for the year were the lowest since 1919, and for the first time in over 30 years China yielded first place in world output.

*National defense.*—Because antimony is an important industrial raw material and the United States depends largely on foreign sources of supply, this metal is one of 10 mineral commodities classified as strategic by the Army and Navy Munitions Board. Prior to 1931 the United States obtained a very large part of its antimony imports from China—in 1929, as much as 70 percent. Since this oversea supply could be cut off by a hostile fleet in time of war and since industry would be handicapped seriously if deprived of antimony, our situation at that time was highly unsatisfactory from a national defense viewpoint. In 1931, however, the strategic position was improved materially by establishment of an antimony smelter at Laredo, Tex., to treat Mexican antimony ores, and since that time Mexico has become the principal source of antimony for the United States. Meanwhile Bolivia also has increased its shipments of antimony ores to this country, so that at present the United States obtains a very large part of its antimony from sources in the Western Hemisphere. In 1938 over 85 percent of the total imports were purchased in Mexico and South America.

Notwithstanding this improved strategic position as to antimony there has been agitation for accumulation of a reserve stockpile in the United States, to be used if and when foreign supplies are cut off in a war emergency. The need for this precaution has been emphasized recently by events in Mexico and Bolivia which not only have increased the costs of producing antimony and thus retarded development of resources in those countries but also have threatened the free flow of ores to the United States. In this connection the anticipated passage of the Thomas bill (S. 572—76th Congress) by the Congress of the United States is significant. This bill provides $100,000,000 for the purchase of stockpiles of strategic commodities over a period of 4 years. In addition, the bill authorizes $500,000 to be expended annually for 4 years by the Bureau of Mines and the Geological Survey in investigating domestic resources of deficient strategic minerals. As of June 1, 1939, the bill was awaiting final approval by the Senate and House of Representatives.

*Domestic antimony resources.*—The development of a domestic antimony industry would be the most desirable method of overcoming our dependence on foreign sources of supply. Unfortunately, however, the known resources in the United States offer little hope of achieving that objective. This is evident from the accompanying historical record of production, consumption, and price of antimony in the United States from 1910 to 1938, which shows that under the stimulus of exceptionally high prices during the World War production in 1915 reached a peak of 4,900 tons, or about 35 percent of domestic requirements in that year. The following extracts from a report on strategic

Digitized by Google

minerals recently prepared by the Bureau of Mines and the Geological Survey corroborate the foregoing conclusion:

*Sources.*—Several antimony-bearing minerals are found in many metalliferous deposits that are exploited largely for lead, copper, silver, and gold, and this antimony is finally recovered in the ordinary processes of smelting and treatment. Deposits that contain only stibnite (antimony sulfide), the principal source of antimony, are uncommon. This mineral is commonly found in tabular veins and even though these persist downward in the earth, experience in mining shows that the shoots of antimony sulfide are sporadic and largely confined to shallow surficial zones. For these reasons, the appraisals of reserves of antimony minerals are highly speculative unless the deposits are thoroughly explored.

[1] Includes only antimony recovered in antimonial lead made from domestic antimony and lead ores. Does not include relatively small quantity recovered in other alloys and in compounds, for which data are not available. Antimony contained in domestic antimony ores produced in the United States, most of which was used in producing antimonial lead, was as follows: 1915, 2,100 tons mainly from California, Nevada, and Alaska; 1916, 1,770 tons mainly from Nevada, California, and Alaska; 1917, 390 tons mainly from Nevada; 1918, 50 tons; 1922, 4 tons; 1923, 10 tons; 1924, 33 tons; 1925, 33 tons; 1926, 43 tons; 1928, 42 tons; 1932, 419 tons of which 416 were from Idaho; 1933, 587 tons all from Idaho; 1934, 404 tons all from Idaho; 1935, 559 tons mainly from Idaho; 1936, 755 tons of which 729 were from Idaho; 1937, 1,266 tons of which 768 were from Idaho and the remainder principally from Alaska; and 1938, 650 tons of which 379 were from Idaho and the remainder principally from Alaska.

[2] Includes metal, antimony content of ores, and estimated content of needle or liquated antimony, antimony compounds, type metal, antimonial lead, and other alloys.

[3] Exports under drawback.

[4] 1910, Metal Statistics 1918, p. 365; 1911–38, Metal Statistics 1939, p. 493.

[5] Based on price indexes of U. S. Department of Labor.

[6] Average price divided by wholesale price index.

[7] Data not available.

[8] Includes foreign antimony used at domestic smelters, probably only a small part of the total.

For many years, China has been the source of 50 to 70 percent of the world's supply of antimony, but important sources exist in Mexico, Czechoslovakia, Bolivia, and France. China was the principal source of imports into the United States for many years, but since 1930 has given place to Mexico, which in recent years has contributed 60 percent of domestic imports, mostly in the form of ore. Numerous antimony deposits have been explored in the United States, but the

Digitized by Google

principal sources are a few districts in Idaho, Nevada, California, and Alaska; most of these have been studied and reports on them are available.

*Production from domestic mines.*—The trend in production of metallic antimony in the United States has been determined by conditions at mines (such as the size, grade, and accessibility of the deposits), by the smelting facilities available, and by prevailing prices. As the smelting of antimony ores is not a complicated operation, small smelters have been installed at several mines, but sources of domestic ore large enough to justify construction of a large smelter have not yet been found. Since 1910, annual production has fluctuated widely, largely in response to changes in price. The largest smelter in the United States was erected at Laredo, Texas, to smelt ores from Mexico, and these have since formed the main contribution to domestic supply.

One district in Inyo County has been the principal source of ore in California, but this has been idle since the war, although other deposits have since been discovered and developed nearby. Several districts in Idaho, notably the Yellow Pine, in Valley County, have been noteworthy sources and seem to be capable of increased production at prices slightly higher than those recently prevailing. In Nevada, deposits containing notable amounts of stibnite have been explored at many places, but only a few have been able to ship ore in recent years. Apparently somewhat higher prices would be needed to insure continuous production. Other sources have been explored in Arkansas, Montana, Washington, and Alaska, but the production has been small and intermittent. At high prices, some deposits in the interior of Alaska could become important sources,

A review of the period from 1914 to 1919 shows an abrupt rise, then a steady decline of production in close response to rise and decline of prices. When this record is considered with operations at producing centers, it seems clear that most of the deposits were not physically exhausted but were unable to compete at prevailing prices.

Estimates of probable yield of domestic antimony follow:

*Potential production of antimony in the United States at assumed index prices of 10, 20, and 30 cents per pound, in short tons*

| Assumed index price per pound (cents) | Potential production | | |
|---|---|---|---|
| | First year | Second year | Third year |
| 10 | 1,000–1,500 | 1,000–1,500 | 1,000–1,500 |
| 20 | 2,500–3,500 | 3,000–5,000 | 4,000–6,000 |
| 30 | 5,000–7,500 | 6,000–10,000 | 8,000–12,000 |

*Technologic progress.*—There are no large low-grade disseminated deposits of antimony now known in the United States; therefore, it would appear that even though there was a decided improvement in the technology of the recovery of antimony it could not be applied commercially to the domestic resources.

## DOMESTIC PRODUCTION

*Mine output.*—Antimony produced in the United States is derived from both antimony ores and lead ores. Data on the quantity derived from lead ores are not available, because the Bureau of Mines cannot obtain full information on the output of various commodities made from byproduct antimonial drosses obtained in lead refining. These drosses are used in the manufacture of antimonial lead, other alloys, and chemical compounds such as oxides and sulfides. In 1938, antimonial lead containing 1,871 tons of antimony of domestic origin was produced at primary lead refineries, but this antimony was obtained from antimony ores as well as from lead ores in unknown proportions. Likewise, information on the amount of domestic antimony recovered in other alloys and compounds is not available.

The quantity of antimony contained in domestic antimony ores and concentrates produced in 1938 totaled only 650 tons—49 percent

Digitized by Google

below that in 1937. The decline was due to reduced outputs at the Meadow Creek mine in the Yellow Pine district, Idaho, and the Stampede mine, Kantishna district, Alaska.

The Meadow Creek mine produced concentrates containing 379 tons of antimony in 1938 compared with 754 tons in 1937. The concentrates are largely ferruginous and in addition to antimony contain gold and silver. The product is shipped to the lead smelter at Midvale, Utah. On August 1, 1938, the Bradley Mining Co. took over the assets of the Yellow Pine Co., former operators of the mine. The Stampede mine operated by Morris P. Kirk & Son, Inc., produces a 50- to 55-percent concentrate which is shipped to alloy plants in the United States. Other producers for whom production or shipment of antimony was reported in 1938 included Meyers & Craig, Yreka district, Shoshone County, Idaho; Nevada Antimony Mines, Inc., from the Bloody Canyon mine, Pershing County, Nev.; and J. H. Caustin and Jack Flynn, Lovelock, Nev. The Menardi Metals Co., Los Angeles, Calif., purchased a small quantity of antimony ore from various unnamed producers in California. Statistics on the domestic output of antimony ores and concentrates and the antimony content thereof during the past 5 years are given in the salient statistics table. A large part of the antimony ore produced in the United States is charged to lead furnaces and recovered as antimonial lead.

*Smelter output.*—From 1935 to 1937, inclusive, the only active primary antimony smelter in the United States was that of the Texas Mining & Smelting Co. at Laredo, Tex. In 1938 the Menardi Metals Co. reported the production of antimony at its plant, Los Angeles, Calif. In May 1938 the press reported that the American Smelting & Refining Co. expected to start production of metallic antimony at its Perth Amboy plant, but no production of regulus was reported by the company for 1938.

Production of the Laredo plant from 1933 to 1937 was shown on page 648 of Minerals Yearbook, 1938. Data for 1938 are not available for publication.

The Los Angeles plant reported production of antimony metal from foreign and domestic ores in 1938 for the first time. The antimony is derived largely from livingstonite concentrates produced in Mexico. The principal product of the plant to date has been mercury.

Data on antimonial lead production at primary lead refineries are shown in the accompanying table. These represent only part of the total antimonial lead output, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

*Antimonial lead produced at primary lead refineries, 1934–38, in short tons*

| Year | Production | Antimony content | | | | |
|---|---|---|---|---|---|---|
| | | From domestic ores | From foreign ores [1] | From scrap | Total | |
| | | | | | Quantity | Percent |
| 1934 | 16,607 | 1,657 | 18 | 588 | 2,263 | 13.6 |
| 1935 | 16,384 | 1,110 | 26 | 593 | 1,729 | 10.6 |
| 1936 | 23,230 | 1,434 | 37 | 691 | 2,162 | 9.3 |
| 1937 | 27,524 | 1,636 | 90 | 853 | 2,579 | 9.4 |
| 1938 | 24,123 | 1,871 | 209 | 720 | 2,809 | 11.6 |

[1] Includes lead ores, antimony ores, and metallic antimony.

Digitized by Google

*Secondary production.*—The production of secondary antimony in the United States in 1938 totaled 8,500 tons, compared with 12,340 tons in 1937. Statistics for the past 5 years are shown in the salient statistics table. Additional information is given in the chapter in this volume on Secondary Metals—Nonferrous.

## DOMESTIC CONSUMPTION

Precise data on the consumption of primary antimony in the United States are not available owing to lack of information on dealer and consumer stocks and on the quantity of domestic antimony recovered in alloys other than antimonial lead and in compounds; however, an approximate idea of the trend of consumption can be obtained from the following table, which shows the annual supply available for consumption.

*Primary antimony available for consumption in the United States, 1934–38, in short tons* [1]

| | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Domestic antimony recovered in antimonial lead | 1,657 | 1,110 | 1,434 | 1,636 | 1,871 |
| Imports for consumption (antimony content): | | | | | |
| Antimony ore | 2,891 | 4,587 | 10,545 | 13,818 | 8,322 |
| Needle or liquated [2] | 292 | 946 | 830 | 540 | 63 |
| Compounds [3] | 241 | 502 | 975 | 909 | 336 |
| Type metal, etc | 586 | 209 | 309 | 410 | 355 |
| Regulus | 1,765 | 1,248 | 1,171 | 1,043 | 821 |
| Total available | 7,432 | 8,602 | 15,264 | 18,356 | 11,768 |
| Exports under draw-back | 170 | 251 | 224 | 224 | 211 |
| Available for consumption | 7,262 | 8,351 | 15,040 | 18,132 | 11,557 |

[1] Excludes domestic antimony recovered as miscellaneous alloys, oxides, and other compounds.
[2] Content estimated at 70 percent. [3] Content estimated at 80 percent.

Apparent consumption of primary antimony in 1938 declined 36 percent from 1937. This decrease, however, exaggerates the actual decline in the use of antimony in manufactured products, as consumers probably drew on stocks of raw materials accumulated during 1937 when a threatened shortage of Chinese antimony caused prices to rise to extraordinary levels. One of the principal uses of antimony is in the manufacture of storage batteries. According to the American Bureau of Metal Statistics 92,000 tons of antimonial lead were used for this purpose in 1938 compared with 107,060 tons in 1937. The antimony content of this material ranges from 4 to 12 percent, and while a large part of the total is supplied by battery scrap a substantial quantity of new antimony is required annually to "sweeten" the alloy.

Another extensive use of antimony is in the manufacture of babbitt metals employed in bearings. These are applied widely in automotive equipment, although cadmium-silver bearings have been used extensively in this field during the last few years.

The use of antimony in the manufacture of chemicals declined 37 percent in 1938 compared with 1937. In 1938, 4,393 tons of oxides and other compounds with an estimated antimony content of 3,539 tons were produced, whereas in 1937 (revised figures), 6,992 tons (5,667 content) were made. Figures for the 3 preceding years are as follows: 1936, 4,852 tons (3,940 content); 1935, 3,969 tons (3,227

Digitized by Google

content); and 1934, 2,569 tons (2,101 content). Foreign ores are used largely in the manufacture of antimony chemicals. The principal compound made is the oxide, which is employed extensively as a pigment in sanitary enamelware. In recent years the addition of antimony oxide pigment to nitrocellulose enamels has been gaining.

## FOREIGN TRADE

The following tables show imports and exports of antimony and antimony products.

*Antimony imported for consumption in the United States, 1934–38*

| Year | Antimony ore | | | Needle or liquated antimony | | Antimony metal | | Antimony oxides and other compounds | |
|---|---|---|---|---|---|---|---|---|---|
| | Short tons | Antimony content | | Short tons | Value | Short tons | Value | Short tons | Value |
| | | Short tons | Value | | | | | | |
| 1934 | 8,455 | 2,891 | $158,672 | 417 | $26,761 | 1,765 | $158,414 | 301 | $35,507 |
| 1935 | 14,205 | 4,587 | 544,608 | 1,352 | 165,446 | 1,248 | 250,771 | 628 | 94,783 |
| 1936 | 30,486 | 10,545 | 1,200,132 | 1,185 | 139,784 | 1,171 | 243,474 | 1,219 | 217,505 |

*Estimated antimony content in type metal, antimonial lead, and other alloys imported for consumption in the United States, 1934–38, in short tons* [1]

| Year | Type metal and antimonial lead | Other alloys [2] | Total | Year | Type metal and antimonial lead | Other alloys [2] | Total |
|---|---|---|---|---|---|---|---|
| 1934 | 18 | 568 | 586 | 1937 | [3] 17 | 393 | 410 |
| 1935 | 89 | 120 | 209 | 1938 | [3] 59 | 296 | 355 |
| 1936 | [3] 56 | 253 | 309 | | | | |

[1] For details of gross weight and values see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony.
[3] Type metal only.

*Foreign antimony (regulus or metal) exported from the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 402 | $42,415 | 1937 | 437 | $86,991 |
| 1935 | 318 | 62,167 | 1938 | 711 | 96,836 |
| 1936 | 392 | 56,308 | | | |

In addition to the foreign exports reported above 211 tons of antimony were exported in 1938 in manufactures (chiefly storage batteries) under the draw-back provisions of the tariff law; 224 tons were so exported in 1937. Stocks of needle and liquated antimony and regulus on hand in bonded warehouses amounted to 337 tons at the end of 1938 compared with 649 tons on December 31, 1937.

## PRICES

The downward trend in prices evident at the close of 1937 continued in 1938. The average spot quotation for domestic metal (99.5 percent) in New York was 12.35 cents per pound in 1938 compared with 15.35 cents in 1937. Prices were stable at 13.75 cents throughout the first quarter of the year, but in the latter part of April the market began moving to lower levels as the volume of business continued small. The low for the year—10.75 cents—prevailed the latter part of July and most of August, but as business improved in late summer quotations advanced, reaching 12.25 cents on October 20. This price was maintained until early December, when a temporary slackening in demand forced prices down to 11.25 cents. As the year closed the market became firmer, and the quotation on December 31 stood at 11.75 cents.

Quotations for prompt Chinese metal (99 percent), as reported by the American Metal Market, were maintained at considerably higher levels than those for domestic antimony. The average for 1938 was 14.59 cents, duty paid, which was 2.24 cents above the average for American brands. In previous years the differential seldom had exceeded 0.50 cent per pound. However, one authority stated that it was doubtful if the actual sales price of Chinese metal in 1938 averaged more than 0.25 to 0.50 cent above that of American brands.[2]

On the London Metal Exchange quotations for English brands declined from £81–82 per long ton on January 1, 1938, to £70–71 on July 1, which price was maintained for the rest of the year. Foreign

[2] Henderson, H. P., Review of Antimony Market for 1938: Metals, vol. 9, No. 7, January 1939, pp. 13–15.

Digitized by Google

regulus (in warehouse) was quoted at £63–66 on January 1, £46–48 on July 1, and £52–53 at the close of the year. In China the basis for quotations was changed several times during the year, so that a reliable picture of the trend of prices is not available. The market at Hong Kong was affected by the Sino-Japanese hostilities, and prices trended downward. At the beginning of the year the quotation was £58 per long ton but dropped to £40 in June, July, and August. During the last 4 months of the year the trend was upward, and at the end of the year the quotation was £43.[3]

[1] Source: Metal Statistics, 1939, pp. 487, 495.
[2] No quotations published prior to 1935.
[3] No average due to lack of offerings during greater part of month.

Quotations for antimony ore on January 13, 1938, were reported as follows by Engineering and Mining Journal Metal and Mineral Markets: "Per (short-ton) unit of antimony contained, $1.50 @ $2.00, f. o. b. New York. London, per long-ton unit, 5s. 6d. @ 6s. 3d. for 60- to 65-percent sulfide ore." By August 4, New York quotations had declined to $1.20 @ $1.30 per short-ton unit for 50- to 55-percent ores, $1.35 @ $1.40 for 58- to 60-percent ores, and $1.60 @ $1.70 for 60- to 65-percent ores. London prices for 60- to 65-percent ores were 5s. 3d. @ 5s. 6d. per long-ton unit. At the close of the year the respective prices were $1.20 @ $1.25, $1.30 @ $1.40, $1.40 @ $1.60, and 6s. 3d. @ 6s. 6d.

## WORLD PRODUCTION

World production of antimony in 1938 is estimated at 29,500 metric tons, a decline of about 20 percent from the output in 1937. As measured by exports, production in China dropped 47 percent, and for the first time in many years that country ranked second in world output. Exports from Bolivia increased 32 percent and were the highest on record. Bolivia thus assumed first place in world antimony production, whereas Mexico, with a 24-percent decline in output, dropped from second to third place. Bolivia, China, and Mexico produced 29, 26, and 25 percent, respectively, of the world antimony supply in 1938; the United States produced less than 2 percent.

## REVIEW BY COUNTRIES

*Argentina.*—According to American Vice Consul Robert E. Wilson, of Buenos Aires, the only antimony mine being worked in November 1938 was a property known as El Pabellon situated in the Cerro Granados, Department of Rincanada, Province of Jujuy. Approximately 50 metric tons of sulfide and oxide concentrates were produced in 1937, and during the first 8 months of 1938, 200 tons of oxide ore containing 60 percent antimony were produced. The mine has not been developed sufficiently to permit an estimate of its worth. The National Lead Co. produces about 15 tons of byproduct antimony each year at its lead smelter at Puerto Vilelas (Chaco).

*Canada.*—The new antimony refinery of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail, B. C., was completed and put into operation during the last quarter of the year. The plant treats 10 short tons of silver-refinery byproducts daily, from which about 4 tons of antimony are recovered. No production for 1938

Digitized by Google

was reported officially. Imports of antimony totaled 428 tons in 1938 and 588 tons in 1937.

*China.*—Rail movement of antimony from Changsha to Hong Kong via Canton, initiated the latter part of 1937 after the Yangtze River was closed to commerce, continued in 1938 despite frequent bombings from Japanese airplanes. However, in October Japanese activity in the vicinity of Canton closed the shipping route to Hong Kong, and subsequently shipments from Changsha were diverted to Haiphong, French Indochina, via Kweilin. In March 1939 Howard Donovan, American consul at Hong Kong, reported that antimony shipped via Haiphong would begin to arrive in Hong Kong within 2 or 3 months.

With the general reorganization of the Chinese Government on January 1, 1938, the Hankow Foreign Trade Office and the Antimony Administration at Changsha, both subsidiary to the Natural Resources Commission, were removed from the control of the Military Affairs Commission and placed under jurisdiction of the Ministry of Economy. The Hankow Foreign Trade Office continued to exercise strict control over the sale and exportation of antimony products, although no attempt was made to "squeeze" out private traders. Because of diversion of antimony trade from Hankow to Hong Kong, the price quotations of the Foreign Trade Office were made in Hong Kong currency beginning in May 1938, and early in June the office was moved to Hong Kong.

The usual excellent statistical reviews supplied by Vice Consul Robert M. Taylor from Hankow were received for the first 9 months of 1938, but he was unable to obtain any information after the Japanese occupation of Hankow in late October. A Reuter dispatch from Shanghai dated November 28, 1938, stated that the Japanese intended to press on to the antimony mines and to establish a Japanese antimony monopoly. However, as of May 1939 the mines were still under Chinese control. Unofficial data indicate a decline in production from 8,850 long tons for the first 9 months of 1937 to 7,565 for the same period in 1938. Shipments from Changsha to Hong Kong fell successively in the first three quarters of 1938, and all excess stocks were moved from Hunan Province to Hong Kong in anticipation of the Japanese invasion. On September 30 total stocks in the Hunan consular district were estimated at 837 tons, mostly at Changsha. Collective prices for regulus paid by the Antimony Administration at Changsha ranged from ch $560 to $580 per long ton (U. S. $140 to $145) during the first quarter of 1938. Similar data for the second and third quarters are not available, but from October 10 to 20 the published quotation was ch $436.

Exports for all of 1938 were reported officially as follows: Crude 535 long tons, oxide (etc.) 253 tons, and regulus 7,070 tons; for 1937 the figures were 2,220 tons, 602 tons, and 12,322 tons, respectively.

*Germany.*—The antimony mines at Neustift near Schleiming (Austria), idle in 1937 and 1938, were being reopened early in 1939, apparently with Government aid. Germany's recent conquests have not improved her antimony position, as Austria depended largely on imported metal, and Czechoslovakia's production only equaled local requirements. Germany imported 3,643 metric tons of antimony metal in 1938 and 2,672 tons in 1937.

Digitized by Google

*Japan.*—Little information is available on the progress made in the various projects to increase Japan's antimony production mentioned in Minerals Yearbook, 1938. Presumably local deposits have not equaled expectations, as a trade report in August 1938 stated that a Japanese concern had arranged to import 200 metric tons of antimony ore per month from Bolivia.

*Mexico.*—A unique source of antimony is the deposit of livingstonite, a rare mercury-antimony sulfide ($HgS.2Sb_2S_3$), in the Huitzuco district, Guerrero. The crude ore is treated by flotation, and the concentrate is shipped to the plant of the Menardi Metals Co., Los Angeles, Calif., where both refined mercury and antimony are produced.[4] In 1937, 30,184 short tons of ore with an average content of 1.25 percent antimony and 0.315 percent mercury were produced, and from January 1 to November 30, 1938, 46,822 tons, averaging 0.96 percent antimony and 0.24 percent mercury, were treated. In the latter part of 1938, 3 to 4 tons of concentrate containing 25 to 30 percent antimony and 7 to 11 percent mercury were being produced daily.

In August 1938 a 12-percent export tax was imposed on virtually all products shipped from Mexico. The tax presumably was designed to give the Government the benefits accruing to exporters from depreciation in the foreign exchange value of the peso. It is levied on the basis of an official valuation of commodities established monthly; in the case of metals and ores, one value apparently applies to all products regardless of the form in which they are exported and notwithstanding the fact that low-grade ores are less valuable per unit of metal than high-grade products. The tax thus has tended to be unduly burdensome on the producers of low-grade antimony ores, shipments of which are said to have been curtailed sharply in 1938.

*Yugoslavia.*—The Podrinje Consolidated Mines, Ltd., completed its modernized smelter, which now has an annual capacity of 1,800 tons of antimony. Another smelter is reported to have been completed at the Zajaca mine near Loznica, owned by Montania A. G.

## CADMIUM

In 1938 the cadmium industry experienced one of the worst years in its history. In contrast to the extraordinary demand and ascending prices in the 3 previous years, consumption fell abruptly and prices collapsed. At the close of the year the New York quotation for commercial sticks was 60 cents per pound compared with official quotations of $1.25 and reported sales of prompt metal at $2.00 during the acute shortage in the summer of 1937. According to trade reports the domestic price situation was aggravated further by the 50-percent reduction in the import duty (from 15 to 7.5 cents per pound), effective January 1, 1939, negotiated in the trade agreement with Canada signed November 17, 1938.

The statistical record indicates a 34-percent decline in apparent consumption of cadmium in all forms, but sales of metal by domestic producers to domestic consumers dropped 54 percent. Imports

Digitized by Google

declined 97 percent, and for the first time large exports were reported to the Bureau of Mines. The decline in consumption may be ascribed in part to the 48-percent reduction in automobile production, one of the principal outlets for cadmium as a constituent of bearing metals. According to a well-informed authority, there was a 50-percent decline in this use of cadmium during 1938. Undoubtedly substitutes for cadmium plating, developed during the period of high prices, made additional inroads on the cadmium market in 1938, and consumption of cadmium compounds was much lower.

Despite the sharp reduction in demand, production of cadmium held up remarkably well in 1938. The total output decreased only 13 percent, production of metal 6 percent, and that of compounds (cadmium content) 48 percent. There were two new producers of metallic cadmium in 1938. Figures on production and sales for 1937 and 1938 reveal that producers' stocks of metal at the end of 1938 totaled at least 1,750,000 pounds.

World production, estimated at 4,200 metric tons in 1938, was virtually unchanged from 1937. Declines in the United States, Australia, Canada, and South-West Africa were offset by gains in Belgium, Germany, Poland, and probably Italy. London prices declined steadily throughout the year.

*Cadmium produced, sold by producers, imported, and consumed in the United States, 1934–38, in pounds*

| Year | Produced | | | Metallic cadmium sold by producers | Metallic cadmium imported | Apparent consumption |
|---|---|---|---|---|---|---|
| | Metallic cadmium | Cadmium compounds (estimated content) | Total cadmium | | | |
| 1934 | 2,777,384 | 566,700 | 3,344,000 | 2,472,971 | 125,955 | 3,470,000 |
| 1935 | 3,477,091 | 507,400 | 3,984,000 | 4,023,900 | 185,387 | 4,169,000 |
| 1936 | 3,633,495 | 626,800 | 4,260,000 | 3,626,669 | 576,139 | 4,836,000 |
| 1937 | 3,995,739 | 828,000 | 4,824,000 | 3,801,321 | 828,535 | 5,652,500 |
| 1938 | 3,753,323 | 431,000 | 4,184,000 | [1] 2,191,035 | 22,582 | 3,748,000 |

[1] Of this quantity 458,283 pounds were exported.

## DOMESTIC PRODUCTION

The cadmium production shown in the foregoing table includes metal derived from domestic and foreign raw materials refined in the United States. Data are not available on the quantity produced from each source, but foreign metal apparently represents a substantial part of the total. In 1938 Mexico reported shipments of crude materials to the United States containing 838 tons of cadmium compared with approximately 683 tons in 1937.

Cadmium is derived chiefly as a byproduct from zinc ores, and its production depends to some extent on the rate of zinc output. In recent years, however, stocks of cadmium-bearing flue dusts and similar products accumulated over a period of several years have made possible an increase in cadmium production that is relatively more rapid. By 1937 much of this material had been used, and in 1937 and 1938 production was limited to some extent to that derived from current zinc operations. A more severe decline in output in 1938 was avoided by new plants coming into production and the increased imports of

Digitized by Google

crude materials from Mexico. New producers of metallic cadmium in 1938 included the Henryetta (Okla.) smelter of the Eagle-Picher Mining & Smelting Co. and the Josephtown (Pa.) plant of the St. Joseph Lead Co. A cadmium dust-recovery plant was completed late in 1937 at the Fort Smith (Ark.) zinc smelter of the Athletic Mining & Smelting Co. The dust is shipped to the East St. Louis plant of the American Zinc Co. of Illinois for conversion. There were no new producers of cadmium compounds in 1938.

A list of producers of both metal and compounds in 1936 was published on page 742 of Minerals Yearbook, 1937. To this should be added the American Steel & Wire Co., Donora, Pa., a new producer of refined cadmium in 1937, and the two new producers in 1938 mentioned above.

A small but increasing quantity of secondary cadmium is recovered from scrap resulting from the manufacture of automobile bearings. This is not included in the statement of production, as it would represent duplication of metal previously reported.

Since the zinc concentrates of the Tri-State region constitute the largest potential source of cadmium in the United States, the following information on the cadmium content of ores from this district is of interest. (The data have been obtained through the courtesy of the Tri-State Zinc and Lead Ore Producers Association.) One series of tests on ores from the various camps in the district indicated an average cadmium content of 0.40 percent for coarse concentrates (30 samples), 0.31 percent for sludge (9 samples), and 0.36 percent for flotation concentrates (48 samples). The content did not vary appreciably between the various parts of the district. An analysis by L. T. Merrill, of the Picher Assay Office, of a sample from 7 tons of sample rejects collected in 1930 gave the following results:

| | *Percent* | | *Percent* |
|---|---|---|---|
| Zinc | 58. 000 | Lime | 0. 670 |
| Iron | 1. 700 | Magnesia | . 508 |
| Lead | 1. 520 | Silica | 4. 990 |
| Copper | . 060 | Carbon dioxide | 1. 081 |
| Cadmium | . 387 | | |
| Sulfur | 30. 837 | | 99. 753 |

In 1937 the district produced 446,890 tons of zinc concentrates which, at an average cadmium content of 0.37 percent, contained approximately 3,300,000 pounds of cadmium. Probably less than one-fourth of this amount actually was recovered in 1937, indicating that a substantial increase in production from this source is possible should market conditions warrant the necessary investment in plant and equipment.

## DOMESTIC CONSUMPTION

The statistical trends in consumption during 1938 have been discussed in the summary at the beginning of the cadmium section of this chapter.

One of the principal uses of cadmium is in bearing metals for high-speed internal-combustion engines. Consumption for this purpose has been estimated at approximately 1,000,000 pounds in 1937 and 500,000 pounds in 1938. According to an authority in the trade, during 1938 there were additional users of cadmium bearings, and all former consumers continued to employ them. As stated in Minerals

Digitized by Google

Yearbook, 1938, some difficulty has been experienced from corrosion of cadmium alloys by lubricants, and several methods of overcoming it have been developed. J. G. Ryan (U. S. Patent 2,116,851, May 10, 1938) states that the addition of 0.1 to 5.0 percent antimony to cadmium-silver alloys improves their resistance to corrosion.

Several articles relating to the uses of cadmium were published recently. Alloys were discussed by Wilson and Wick[5] and Monselise.[6] Erskine [7] has described methods for coloring cadmium electrodeposits, and Rinker [8] and others [9] discussed electroplating technique. Two United States patents (Nos. 2,115,080 and 2,134,055) were issued during 1938 on processes for making cadmium red pigments.

## FOREIGN TRADE

Official statistics record separately only the imports of metallic cadmium. There is a limited import and export trade in cadmium compounds, and some metal is known to have been exported before 1938, but the quantities involved are believed to be relatively unimportant. In 1938, however, there was considerable exportation of cadmium metal. Reports to the Bureau of Mines indicate that four companies shipped 458,283 pounds abroad in 1938. Exports of cadmium with benefit of draw-back, mostly in lithopone, totaled 36,081 pounds in 1938 and 23,508 in 1937. Imports of metallic cadmium decreased very substantially in 1938, being only 22,582 pounds compared with 828,535 in 1937. Of the 1938 total, Belgium supplied 20,067 pounds; Italy, 2,240; Poland, 220; and Germany, 55. Of the quantity received in 1937, Canada supplied 270,620 pounds; Belgium, 250,878; United Kingdom, 139,405; Norway, 76,940; Germany, 34,562; Poland, 27,557; Australia, 22,400; France, 3,968; and Netherlands, 2,205. The average value of the cadmium imported in 1938, as reported by the Customs Bureau, was $1.35 per pound compared with $1.30 in 1937 and $0.71 in 1936. The United States also imports crude materials containing cadmium for refining. Shipments of this type of material from Mexico to the United States during 1938 contained 838 tons of cadmium compared with 683 tons in 1937.

## PRICES

According to Engineering and Mining Journal Metal and Mineral Markets, the average price of cadmium in 1938 was 98.0 cents per pound compared with $1.223 in 1937, 97.8 cents in 1936, 70.5 cents in 1935, and 55 cents from 1932 to 1934. In 1929 the price ranged from 80 to 95 cents per pound. Incomplete data obtained from producers by the Bureau of Mines indicate that the average value realized on sales of metallic cadmium in 1938 was 75 cents per pound compared with $1.14 in 1937, 80 cents in 1936, and 50 cents in 1935.

At the beginning of 1938 patented shapes for platers were quoted at $1.35 per pound, New York, and producers' minimum price for quantity business in commercial sticks was $1.00. With production maintained at fairly high levels and consumption waning, stocks began to accumulate and prices weakened. On April 1 both quotations were reduced 15 cents per pound, and subsequent cuts in August and September brought prices down to 65 cents for commercial sticks and 95 cents for platers' shapes. On November 24 a further reduction to 60 and 85 cents, respectively, was announced. This was attributed by the trade to the Canadian Trade Agreement signed on November 17, under which the United States import duty on cadmium was reduced from 15 to 7.5 cents per pound, effective January 1, 1939. No change in quotations was made during the remainder of the year.

At the close of the year, Engineering and Mining Journal Metal and Mineral Markets (December 29, 1938, p. 3) issued the following statement regarding publication of monthly average cadmium prices during 1939:

> In addition to the monthly average price of cadmium that we have been publishing for the last 9 years, a monthly average will be established in 1939, beginning with January, on the price quoted by producers on ordinary commercial shapes, quantity business.
>
> The old average, accepted in the industry as representing the average of the producers' and platers' quotations, will be continued because several contracts have been made on that basis.
>
> Confusion over cadmium quotations has obtained for a number of years, largely because of the numerous changes that have occurred in reference to new outlets for the metal. Platers market a fairly large poundage at a premium over the producers' quotations, delivering patented shapes and servicing the process used in plating as well. Not so many years ago the platers virtually dominated the market because of the large proportion of the metal that was consumed in the plating industry. Since 1936, however, the automotive industry has found extensive use for cadmium in the production of bearings for internal-combustion motors. The price situation appears to be clearing, and we find that a need now exists for a straight producer's quotation.

According to Quin's Metal Handbook, London quotations (listed as nominal) declined steadily throughout 1938 from 5s. 2.5 d. ($1.30) per pound on January 1 to 2s. 1d. (48.0 cents) on December 31. During the first 5 months of 1938 London prices exceeded or approximately equaled New York quotations, but for the remaining months quotations in London were approximately 7 to 12 cents under the domestic market.

## WORLD PRODUCTION

Statistics from countries that produced 86 percent of the total output in 1937 indicate that world production of cadmium in 1938 was virtually the same as in 1937. The United States contributed 45 percent of the estimated total for 1938, some of which was from imported crude materials. Declines were noted in the outputs of Australia, Canada, and South-West Africa, as well as in the United States, whereas Belgium, Germany, and Poland achieved substantial increases. Italy probably produced more cadmium in 1938 than in 1937, but statistics thereon are not available at this time.

[1] Exports.
[2] Data not available. Estimate included in total.
[3] Estimated production.
[4] The Mexican Government reports the total cadmium content of material produced in Mexico as follows: 1934, 384,714 kilos; 1935, 597,527 kilos; 1936, 535,017 kilos; 1937, 619,792 kilos; and 1938, 762,398 kilos. This material is exported for treatment elsewhere; therefore, to avoid duplication of figures, the data are not included in this table.
[5] Estimated cadmium content.

## REVIEW BY COUNTRIES

*Australia.*—The Electrolytic Zinc Co. of Australia, Ltd., recovered 35 long tons of cadmium from Tasmanian zinc ores and 147 tons from other ores, chiefly from Broken Hill. In 1937, 45 tons were derived from Tasmanian ores and 162 tons from other ores. Cadmium by-products are recovered at the Port Pirie lead smelter, South Australia. Forty-six tons of precipitates were produced in 1937 and presumably shipped to Risdon for refining. Data are not available on the cadmium content of these products and the quantity produced in 1938.

*Canada.*—Cadmium is obtained as a byproduct at the electrolytic zinc plants at Trail, B. C., and Flin Flon, Manitoba. Production at Trail increased from 218 short tons in 1937 to 255 in 1938, whereas that at Flin Flon declined from 154 to 94 tons owing to the fact that stocks of precipitates accumulated before the cadmium plant was opened in 1936 were exhausted in June 1938.

*Germany.*—The increase in output in 1938 reflects the larger production of zinc in that year. Cadmium is recovered at the Magdeburg electrolytic zinc plant and at the Oker vertical-retort smelter. The Magdeburg plant can produce 150 to 180 metric tons of cadmium annually. According to American Consul Sydney B. Redecker, Frankfort on the Main, Germany treats cadmium-bearing flue dusts from South-West Africa, imports of which have been as follows: 64 tons in 1934, 145 in 1935, 99 in 1936, and 133 in 1937. Figures for 1938 are not available.

Despite the increased output in 1938 there was a scarcity of cadmium. Imports increased considerably, but data thereon are not recorded separately. Norway, Poland, Italy, and the United Kingdom supplied most of the metal imported in 1938.

Digitized by Google

*Italy.*—The new 100-ton-per-year plant at Porto Marghera was put into operation in June 1938. Italy's production now exceeds domestic requirements.

*Japan.*—The Metal Bulletin, London (Jan. 10, 1939), reports that Japanese demand for cadmium is supplied largely by production from the Miike works of Mitsui Mining Co., the Hosokura and Naoshima works of the Mitsubishi Mining Co., and the Tsu plant of Nippon Soda Co. These three companies control the trade in cadmium through a cartel.

*Norway.*—Cadmium is recovered as a byproduct from the electrolytic zinc plant of Det Norske Zinkkompani A. S. of Eitrheim, the only producer of zinc and cadmium in Norway.

*South-West Africa.*—Cadmium-bearing flue dusts containing about 30 percent cadmium are produced as a smelter byproduct at the Tsumeb copper-lead mine. In 1938 exports amounted to 672 metric tons compared with 436 tons in 1937. Shipments in 1938 were consigned to Antwerp, Belgium.

| Refined platinum metals | 739 | World production | 745 |
| New metals recovered | 739 | | |

The outstanding statistical feature of the platinum industry in 1938 probably was the phenomenal increase in production in Alaska. Although the United States is by far the largest consumer of platinum metals in the world, prior to 1935 only small quantities were produced annually from domestic sources. For example, the average annual production was only about 8,300 ounces from 1925 to 1934, inclusive. Since then, however, domestic output (chiefly of placer platinum in Alaska) has advanced progressively from 11,552 ounces in 1935 to 49,380 ounces in 1938.

[1] Subject to revision.

[2] In 1937 includes 9,255 ounces of new platinum from domestic sources, comprising 4,466 ounces derived from crude placer platinum, 28 ounces recovered from ore, and 4,761 ounces obtained from domestic gold and copper ores as a byproduct of refining; in 1938 includes 6,376 ounces of new platinum from domestic sources, comprising 2,590 ounces derived from crude placer platinum, 25 ounces recovered from ore, and 3,761 ounces obtained from domestic gold and copper ores as a byproduct of refining.

Digitized by Google

In addition to now being the fourth largest source of supply of platinum metals, the United States is an important refining center and occupies a prominent position in the international platinum trade. In 1938, for example, 36,213 ounces of new platinum metals and 64,291 ounces of secondary platinum metals were recovered by domestic refiners, 161,186 ounces of unmanufactured platinum metals were imported for consumption, and 33,635 ounces of platinum and allied metals (ingots, sheets, wire, alloys, and scrap) and a considerable quantity of placer platinum were exported.

Despite the much larger output of domestic placer platinum, the bulk of the new platinum metals recovered by refiners in the United States in 1938, as in previous years, was derived from crude platinum from foreign sources, notably Colombia, as most of the Alaska platinum was refined abroad. Most of the refined new platinum metals now consumed in the United States come from the United Kingdom; the metals are recovered there chiefly as a byproduct in refining nickel-copper matte from the Sudbury district of Ontario and, to smaller extents, from matte from the Rustenburg district of the Union of South Africa and placer platinum from the Goodnews Bay district of Alaska.

*Shifts in sources of supply.*—The year 1938 probably marks the beginning of another period of transition in world production of platinum metals. During the present century and especially during the past two decades, the sources of supply of platinum metals have undergone several changes, owing chiefly to the decline in Russian output, the increased production in Colombia following the introduction of dredges, the successful recovery of platinum-group metals from the nickel-copper ore of the Sudbury (Ontario) district and from the oxidized and sulfide ores of the Transvaal, and the inauguration of mechanized equipment at the placer deposits in the Goodnews Bay district, Alaska.

Prior to 1900 the U. S. S. R. was the source of probably 90 percent of the platinum metals produced in the world, most of the remainder coming from Colombia. From 1900 to 1914 the U. S. S. R. contributed about 95 percent and Colombia the bulk of the remainder. The World War and the subsequent revolution had a depressing effect on the production of platinum metals in the U. S. S. R., and the output dropped to a low of about 20,000 ounces in 1921. Meanwhile, in Colombia the Government became stable, engineering methods were introduced, and production advanced fairly rapidly. Consequently, from 1915 to 1924 Colombia supplied about one-third of the world output, whereas the share of the U. S. S. R. fell to about one-half. Canada and the United States furnished the bulk of the remainder.

After several years devoted to experimental refining and to the development and selection of processes for the recovery of precious metals from the nickel-copper ore of the Sudbury (Ontario) district, a refinery was built in 1924 at Acton, England, to handle annually some 30,000 ounces of platinum metals. Refining at Acton was begun in 1925, and 16,980 ounces of platinum metals were produced there. As production of nickel and copper continued to mount, the annual capacity of the Acton refinery was enlarged to 300,000 ounces of platinum metals. In 1930 Canada recovered 68,000 ounces and became the second largest producer of platinum metals; in 1934, with an

Digitized by Google

output of 200,000 ounces, it succeeded the U. S. S. R. as the world's largest producer. Canadian output increased to 259,000 ounces in 1937 and to 292,000 ounces in 1938.

Although osmiridium had been known to occur in the Witwatersrand district of the Transvaal since its discovery in 1892, it was not until 1921 that regular production was begun at several of the larger mines on the Far East Rand. From 510 ounces in 1921, output increased to 5,764 ounces in 1924 and has averaged 5,779 ounces annually during the decade 1929–38.

Almost simultaneously with the first recovery of osmiridium on a large scale on the Rand came the opening of the platinum deposits in the Waterberg district of the Transvaal, followed in the latter part of 1924 by the important discoveries in the Lydenburg district of the same Province. The first production (10,545 ounces) of platinum metals from these districts was recorded in 1926. The Waterberg district had a short-lived and altogether disappointing history. Important discoveries were made in the Potgietersrust field during 1925 and shortly thereafter in the Rustenburg district. In 1930 production of platinum metals in the Lydenburg, Potgietersrust, and Rustenburg districts had reached 55,342 ounces; in consequence, the Union of South Africa ranked as the third largest producing country, Colombia dropping to fourth.

Despite the fact that operations were discontinued in the Potgietersrust and Lydenburg districts after 1930, the Rustenburg district with a production of 47,163 ounces of platinum metals in 1931 still ranked slightly ahead of Colombia. In 1932 and 1933, however, production dropped to 9,246 and 2,386 ounces, respectively, owing to the drastic decline in sales, which caused suspension of operations in the Rustenburg district from April 1932 to July 1933. Consequently, Colombia regained third place in 1932 and retained it through 1935. With resumption of operations in August 1933 production in the Rustenburg district averaged about 34,000 ounces annually during the 3 years 1934–36. Meanwhile, with recognition of the necessity of treating sulfide ore, prompted by the approaching exhaustion of oxidized ore in the Rustenburg group of mines, experiments were carried out on the technical problems, apparently with much success. In 1937 the milling capacity of the Rustenburg plant was increased to 20,000 tons a month to provide crushing and sorting equipment for handling sulfidic ore, and a smelting plant to treat the concentrates produced from the sulfides was completed and put into operation in November. As a consequence, production in the Rustenburg district increased to 39,625 ounces in 1937 and reached an all-time record of 68,683 ounces in 1938.

Prior to 1935 the United States had contributed only a negligible quantity to the world output of platinum metals. For example, during the 10 years 1925–34 production averaged only about 8,300 ounces annually—1,000 ounces of placer platinum, 600 ounces from palladium-bearing copper ore, and 6,700 ounces as byproducts of gold and other metals. Although important deposits of placer platinum were discovered in the Goodnews Bay district of Alaska about 1926, only a small quantity was produced through 1933. Following consolidation of claims and installation of dragline scraper equipment in 1933, production of placer platinum in Alaska increased progressively from 3,101 ounces in 1934 to 9,823 ounces in 1937. Concurrently, by-

Digitized by Google

product production from gold and other metals advanced from 2,335 to 10,578 ounces.

The successful use of dragline-scraper equipment in Alaska led to installation and completion of a dredge with 8-foot buckets late in 1937. Consequently, production of platinum metals in the United States jumped to 49,380 ounces in 1938—42,043 ounces of placer platinum, 7,247 ounces recovered from gold and copper refining, and 90 ounces from platinum-bearing ore. Thus, the United States attained the rank of fourth largest producer of platinum metals in 1938.

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1938, inclusive. The prominent position of Canada since 1930 and especially since 1934 is strikingly revealed, as

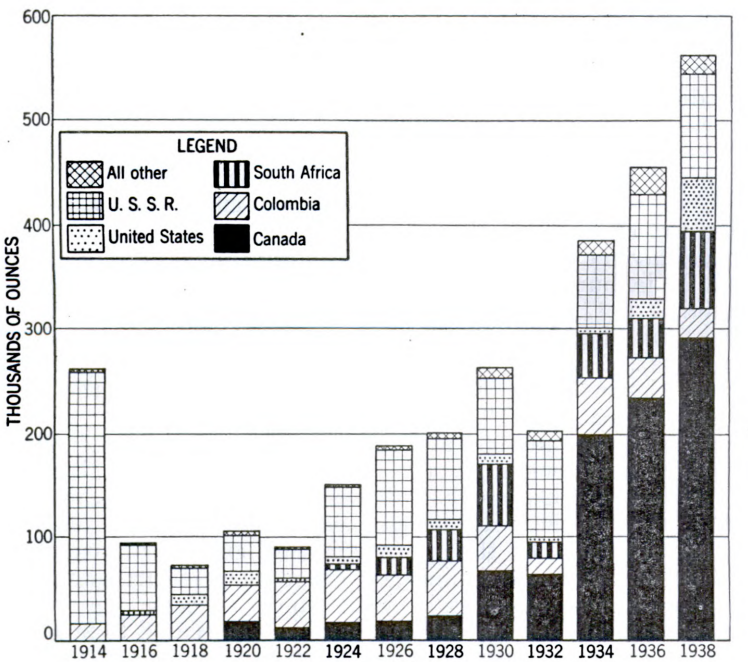

FIGURE 1.—Trend in world production of platinum metals, 1914-38.

well as the rise in production in the United States since 1936. The figures plotted for the U. S. S. R. for 1918, 1920, 1922, 1936, and 1938 are rough estimates of production of crude-platinum metals, whereas those for 1930, 1932, and 1934 are exports of refined platinum.

## CRUDE PLATINUM

*Production.*—Mine returns for 1938 indicate a production of 41,000 troy ounces of crude platinum in Alaska, 1,000 ounces in California, and 43 ounces in Oregon—a total of 42,043 ounces. Comparable figures for 1937 are 9,823 ounces in Alaska, 935 ounces in California, 3 ounces in Nevada, and 42 ounces in Oregon—a total of 10,803 ounces. Most of the production in Alaska came from placers in the Goodnews Bay district south of the mouth of the Kuskokwim River.

Digitized by Google

Smaller quantities were recovered in placer-gold mining in the Koyuk district, Seward Peninsula. Some platinum metals, especially palladium, also were obtained by reworking the tailings from earlier lode mining in the Ketchikan district, Kasaan Peninsula. In California most of the platinum produced was a byproduct of dredges working the gold placers in Merced, Placer, Sacramento, Shasta, Tehama, Trinity, and Yuba Counties. The principal production in Oregon came from the ocean beach near Cape Blanco in Curry County.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1938, 7,247 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores compared with 10,578 ounces in 1937.

*Purchases.*—Platinum refiners in the United States reported purchases of domestic crude platinum from the following sources in 1938: Alaska, 3,658 ounces; California, 1,308 ounces; and Oregon, 27 ounces—a total of 4,993 ounces (7,537 ounces in 1937). Refiners in the United States also reported purchases of 28,324 ounces (34,703 ounces in 1937) of foreign crude platinum in 1938—23 ounces from Canada, 24,604 ounces from Colombia, 1,894 ounces from Ethiopia, 18 ounces from the Philippine Islands, and 1,785 ounces from the Union of South Africa.

*Prices.*—Buyers reported purchases at $20.94 to $33 an ounce for domestic and $20.15 to $31.34 an ounce for foreign crude platinum in 1938.

## REFINED PLATINUM METALS

*New metals recovered.*—Reports from refiners of crude platinum, gold bullion, and copper indicate that 36,213 ounces of platinum metals were recovered in the United States from these sources in 1938, a decrease of 20 percent from 1937. It is estimated that 10,599 ounces of the total output in 1938 were derived from domestic sources.

*New platinum metals recovered by refiners in the United States in 1938, by sources, in troy ounces*

| | Platinum | Palladium | Iridium | Osmiridium | Others | Total |
|---|---|---|---|---|---|---|
| Domestic: | | | | | | |
| Crude platinum | 2,590 | 23 | 383 | ---- | 266 | 3,262 |
| Ore | 25 | ---- | ---- | ---- | 65 | 90 |
| Gold and copper refining | 3,761 | 3,429 | 57 | ---- | ---- | 7,247 |
| | 6,376 | 3,452 | 440 | ---- | 331 | 10,599 |
| Foreign: Crude platinum | 24,068 | 201 | 807 | 384 | 154 | 25,614 |
| Total recovery: 1938 | 30,444 | 3,653 | 1,247 | 384 | 485 | 36,213 |
| 1937 | 36,174 | 5,945 | 1,998 | 640 | 501 | 45,258 |

*New platinum metals recovered by refiners in the United States, 1934–38, in troy ounces*

| Year | Platinum | Palladium | Iridium | Osmiridium | Others | Total |
|---|---|---|---|---|---|---|
| 1934 | 43,392 | 1,471 | 1,588 | 585 | 238 | 47,274 |
| 1935 | 37,284 | 1,432 | 2,438 | 449 | 457 | 42,060 |
| 1936 | 39,728 | 4,682 | 1,678 | 541 | 317 | 46,946 |
| 1937 | 36,174 | 5,945 | 1,998 | 640 | 501 | 45,258 |
| 1938 | 30,444 | 3,653 | 1,247 | 384 | 485 | 36,213 |

*Secondary metals recovered.*—In 1938, 64,291 ounces of secondary platinum metals were recovered from the treatment of scrap metal, sweeps, and other waste products of manufacture that contain platinum, a decrease of 11 percent from 1937.

*Secondary platinum metals recovered in the United States, 1934–38, in troy ounces*

| Year | Platinum | Palladium | Iridium | Others | Total |
|---|---|---|---|---|---|
| 1934 | 35,494 | 5,606 | 1,328 | 1,328 | 43,756 |
| 1935 | 47,107 | 7,852 | 2,191 | 1,975 | 59,125 |
| 1936 | 55,959 | 6,786 | 2,204 | 1,217 | 66,166 |
| 1937 | 55,926 | 12,680 | 2,320 | 1,280 | 72,206 |
| 1938 | 44,654 | 13,489 | 2,150 | 3,998 | 64,201 |

*Prices.*—Refiners reported the following prices for platinum in 1938: High $43, low $24, and average for the year $33.83 an ounce compared with $76, $28, and $46.84 an ounce, respectively, for 1937. They gave the following prices for palladium: High $28, low $17, and average for the year $23.21 an ounce compared with $28.50, $18, and $23.21 an ounce, respectively, for 1937.

*Consumption.*—The accompanying table shows sales of platinum metals to domestic consumers by refiners in the United States in 1938. The figures include sales of platinum metals recovered from crude platinum, gold bullion, copper and nickel bullion and matte, electrolytic muds, and scrap materials and sweeps; in addition they include sale of imported platinum metals that are handled by domestic refiners. Sales by refiners totaled 127,306 ounces in 1938 compared with 172,130 ounces in 1937.

The uses of the platinum-group metals are many and varied. The most widely used metal of the group is platinum itself, which constituted 87,568 ounces (68.8 percent) of the total platinum metals sold by domestic refiners in 1938. The largest use of platinum is in jewelry, where rich color and intrinsic value are desirable factors. About 51 percent (44,654 ounces) of the total sales of platinum by domestic refiners in 1938 went to the jewelry trade compared with 52 percent (49,848 ounces) in 1937. Although platinum and its companion metals are generally associated in the public mind with jewelry, they have diversified industrial uses. For example, the chemical industry, the second-largest consumer of platinum, purchased 14,328 ounces from domestic refiners in 1938 (18,300 in 1937), the dental industry 12,324 ounces (11,115 in 1937), and the electrical industry 5,645 ounces (9,465 in 1937).

Palladium, which is about half as common as platinum but less costly, is adapted to many of the same uses as platinum. It com-

Digitized by Google

prised 35,073 ounces (27.5 percent) of the total platinum metals sold by domestic refiners in 1938. The largest consumer of palladium in 1938 was the dental industry, which purchased 18,833 ounces (54 percent of the total) from domestic refiners. The electrical and jewelry industries are the next largest consumers of palladium, and small quantities are used in the manufacture of chemical ware.

Iridium, best known as a hardening addition to platinum, ranks third among the platinum-group metals according to consumption. Of the total sales of platinum metals in 1938, 3,297 ounces (2.6 percent) were iridium.

Sales of the other platinum metals—rhodium (useful as an alloying element with platinum and palladium) and the still rarer ruthenium and osmium (used as hardening additions in special-purpose alloys)—are small and amounted to only 1.1 percent of the total for the group in 1938.

*Platinum metals sold by refiners in the United States in 1938, by domestic consuming industries, in troy ounces*

| Industry | Platinum | Palladium | Iridium | Others | Total | Percent of total |
|---|---|---|---|---|---|---|
| Chemical | 14,328 | 402 | 143 | 159 | 15,032 | 12 |
| Electrical | 5,645 | 10,447 | 616 | 231 | 16,939 | 13 |
| Dental | 12,324 | 18,833 | 148 | 34 | 31,339 | 25 |
| Jewelry | 44,654 | 5,356 | 2,358 | 316 | 52,684 | 41 |
| Miscellaneous and undistributed | 10,617 | 35 | 32 | 628 | 11,312 | 9 |
| | 87,568 | 35,073 | 3,297 | 1,368 | 127,306 | 100 |

The apparent consumption of platinum in the United States, as calculated from statistics on production, imports, and exports, is given in the following table.

*Apparent consumption of platinum in the United States, 1936–38, in troy ounces*

| Year | Recovered by domestic refiners | | | Imports of ingots, bars, sheets, or plates | Exports (unmanufactured and manufactures, estimated) | Apparent consumption |
|---|---|---|---|---|---|---|
| | Primary | Secondary | Total | | | |
| 1936 | 39,728 | 55,959 | 95,687 | 52,013 | 46,000 | 101,700 |
| 1937 | 36,174 | 55,926 | 92,100 | 62,052 | 50,000 | 104,000 |
| 1938 | 30,444 | 44,654 | 75,098 | 44,091 | 27,000 | 92,000 |

*Stocks.*—On December 31, 1938, 117,911 ounces of platinum metals were in the hands of refiners compared with 99,499 ounces at the end of 1937.

*Stocks of platinum metals in the hands of refiners in the United States, Dec. 31, 1934–38, in troy ounces*

| Year | Platinum | Palladium | Iridium | Others | Total |
|---|---|---|---|---|---|
| 1934 | 41,370 | 26,377 | 8,269 | 7,905 | 83,921 |
| 1935 | 50,265 | 27,807 | 9,202 | 6,273 | 93,547 |
| 1936 | 56,886 | 29,853 | 8,943 | 8,235 | 103,917 |
| 1937 | 60,236 | 21,942 | 9,785 | 7,536 | 99,499 |

## FOREIGN TRADE [1]

*Imports.*—Imports into the United States of platinum metals were 161,189 ounces in 1938, compared with 206,937 ounces in 1937. The principal sources of imported platinum metals in 1938 were the United Kingdom (101,987 ounces), the U. S. S. R. (31,431 ounces), and Colombia (22,251 ounces). Imports of palladium (chiefly from the United Kingdom) decreased to 26,858 ounces in 1938 from 45,427 in 1937.

*Platinum metals imported for consumption in the United States, 1934–38*

| Year | Troy ounces | Value | Year | Troy ounces | Value |
|---|---|---|---|---|---|
| 1934 | 174,312 | $4,157,518 | 1937 | 206,937 | $7,418,364 |
| 1935 | 164,149 | 4,228,022 | 1938 | 161,189 | 4,366,912 |
| 1936 | 210,440 | 5,996,034 | | | |

*Platinum metals imported for consumption in the United States, 1937–38, by metals*

| Metal | 1937 | | 1938 | |
|---|---|---|---|---|
| | Troy ounces | Value | Troy ounces | Value |
| Platinum: | | | | |
| Ores of platinum metals (platinum content) | 1,186 | $43,481 | 3,263 | $71,504 |
| Grain and nuggets | 24,405 | 922,795 | 26,176 | 688,166 |

## PRODUCTION IN FOREIGN COUNTRIES

*Belgian Congo.*—The production of platinum and palladium in the Belgian Congo was 2,122 and 12,507 ounces, respectively, in 1937 compared with 3,183 and 12,571 ounces in 1936.

*Canada.*—Recoveries of platinum metals from the nickel-copper ores of the Sudbury district of Ontario were 161,310 ounces of platinum and 130,893 ounces of other platinum-group metals in 1938 compared with 139,355 ounces of platinum and 119,829 ounces of other platinum-group metals in 1937.[2] Sales of platinum metals by the International Nickel Co. of Canada, Ltd., were 193,195 ounces in 1938 compared with 188,756 ounces in 1937.

Placers in British Columbia yielded only 7 ounces of stream platinum in 1938 compared with 22 ounces in 1937.

*Colombia.*—Colombia exported 29,460 ounces of crude platinum in 1938 (29,315 in 1937). Of the 1938 exports, 52 percent went to the

[2] Dominion Bureau of Statistics, Preliminary Report on the Mineral Production of Canada During the Calendar Year 1938: Ottawa, 1939.

Digitized by Google

United States, 47 percent to Germany, and the remainder to France and Japan.

The South American Gold & Platinum Co. produced 20,714 ounces of crude platinum and 63,622 ounces of crude gold in 1938 compared with 18,345 ounces of crude platinum and 42,956 ounces of crude gold in 1937.

*Germany.*—Although the output of platinum metals in Germany is confined to small quantities of platinum and palladium recovered as byproducts in the treatment of copper ores, the country is important in the international platinum trade. Imports of platinum metals and alloys into Germany were 140,482 ounces in 1938 (121,076 ounces in 1937). The chief sources of supply in 1938 were Great Britain (69,388 ounces), the Netherlands (15,268 ounces), the United States (12,423 ounces), and Colombia (12,011 ounces). Exports of platinum metals and alloys from Germany were 32,569 ounces in 1938, of which 18,323 ounces went to Switzerland.

*Platinum metals and alloys imported into and exported from Germany, 1934–38, in ounces*

| Year | Imports | Exports | Year | Imports | Exports |
|---|---|---|---|---|---|
| 1934 | 73,641 | 72,304 | 1937 | 121,076 | 23,512 |
| 1935 | 84,981 | 102,288 | 1938 | 140,482 | 32,569 |
| 1936 | [1] 525,883 | 32,553 | | | |

[1] Includes platinum sweeps, electrolytic muds, used-up platinum contact material, and scrap.

*Union of South Africa.*—According to the Department of Mines and Industries, sales of platinum metals in South Africa in 1938 were 38,862 ounces valued at £223,776 (£5.76 an ounce) compared with 30,125 ounces valued at £237,663 (£7.89 an ounce) in 1937. The average composition of the product shipped in 1937 was platinum 72.53 percent, palladium 19.78 percent, iridium 0.20 percent, osmium and osmiridium 0.12 percent, ruthenium 1.72 percent, and gold 5.65 percent.

The enlarged plant at Rustenburg of Potgietersrust Platinum, Ltd., for handling sulfidic ores was brought into full operation in July 1938.[3] Flotation concentrates are now smelted on the property in a blast furnace and subsequently reduced in bulk by a converter. The matte is shipped to England for further treatment.

Sales of osmiridium in 1938 were 5,233 ounces valued at £34,110 (£6.52 an ounce) compared with 5,667 ounces valued at £37,254 (£6.57 an ounce) in 1937. The average composition of the product shipped in 1937 was osmium 29.92 percent, iridium 26.35 percent, ruthenium 13.48 percent, platinum 11.27 percent, gold 2.51 percent, rhodium 0.48 percent, and undetermined 15.99 percent.

*U. S. S. R.*—No authentic statistics are available on the production of platinum in the U. S. S. R. in recent years. However, it is generally estimated that an annual output of 100,000 ounces of crude platinum has been maintained.

# MINOR METALS

By Paul M. Tyler

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General statement | 747 | Radium and uranium | 755 |
| Beryllium | 748 | Rare earths | 758 |
| Calcium | 751 | Selenium and tellurium | 758 |
| Columbium and tantalum | 751 | Titanium | 759 |
| Indium | 753 | Zirconium | 761 |
| Mesothorium | 754 | | |

During the last decade or two it has become increasingly apparent that the atoms of all the 92 elements can be broken down into smaller atoms, modifying their characteristics and changing their identities. Conversely, it has been found that lighter elements can be made into heavier ones, and new elements have been created that are heavier than any found in nature.

In January 1939, probably first in Copenhagen but almost simultaneously in three American laboratories, it was proved that uranium actually could be cracked in two, and, furthermore, that almost inconceivable amounts of energy (in the neighborhood of 200,000,000 volts) were thus released. A few days later thorium, another heavy element (atomic weight, 232), was split by the million-volt atom-smashing machine at the Carnegie Institution of Washington, and similar results were reported from independent experiments at Johns Hopkins University and (earlier) at the Institute for Theoretical Physics in Copenhagen.

Part of the novelty of these discoveries lies in the hint they give as to methods of tapping the tremendous store of atomic energy, the force that holds all matter together. Previously such concentrations of energy had been known to be produced only in the interior of the sun and the stars. Almost as important is the magnitude of the change in the nature of the atoms. Atom smashing hitherto had succeeded only in abrading or chipping off tiny fragments, producing changes somewhat akin to the spontaneous degeneration of radioactive elements into more or less related substances, but in this latest transmutation the properties of each of the new elements are entirely different from those of the parent element.

The practical importance of these discoveries is yet to be learned. They give promise of the fabrication of rare elements from common ones and the capture for use as industrial power of the limitless, yet still inaccessible, energy sealed in the atoms of terrestrial matter. Enabled now to reshape atomic structures so violently, scientists are better equipped to solve other mysteries of the constitution of matter and to explore further the mechanics of creation of the universe.

Digitized by Google

Masurium (element 43), one of the products of this major cleavage of uranium, is an element so rare in nature that the claim of the Noddacks that they discovered it some years ago has been questioned. Conclusive verification is believed also to be lacking of the existence of illinium (61), of eka-iodine or "alabamine" (85), and of eka-cesium or "virginium" (87). Obviously none of these elements is likely to be found on the earth's surface except in amounts too minute to be important commercially. Knowledge of rhenium likewise would be confined to spectroscopic data and scientific conjecture had it not chanced to be concentrated in the slime from an industrial process. Only this accident makes it possible to produce rhenium at a potential rate of 1 or 2 tons a year when its richest known ore carries only a fraction of 1 percent of the element. A German journal (Naturwissenschaften) is credited [1] with the suggestion that stable isotopes of elements 43 and 61 may not actually exist; in such case further attempts to isolate them even in a laboratory are foredoomed to failure.

It is impracticable for the Bureau of Mines to report faithfully each year the advances along all frontiers of scientific investigation of metals. For certain of the rarer metals it can scarcely keep pace with quasi-industrial developments. An attempt was made in Minerals Yearbook, 1937, to review the commercial status of every one of the metals, but subsequent reviews for the minor metals mention only those for which new information has come to the author of the chapter. More specifically it may be said that the omission of reference to certain elements in the following review does not imply that such elements are deemed less important commercially or less significant scientifically than those that are discussed in some detail.

## BERYLLIUM

Notwithstanding the great interest displayed by several chemical-manufacturing companies, inventors, and investors and the various rumors of new enterprises engaged in producing beryllium on a more or less large scale, the world output of beryl probably still fails to exceed 750 tons a year. In the United States the commercial supply of the metal and its commercial compounds continues to come entirely from two companies—the Beryllium Corporation of Pennsylvania (Andrew Gahagan, president), Temple (near Reading), Pa.; and the Brush Beryllium Corporation (C. B. Sawyer, president), 3714 Chester Avenue, Cleveland, Ohio.

The Beryllium Corporation of Pennsylvania, which has a cooperative arrangement with Siemens & Halske, the leading German beryllium producer, for the exchange of information and patents, recently has completed a fabricating plant at Reading, Pa., the first to be designed especially for rolling and drawing beryllium alloys. In 1935 this company transferred its plant activities from Michigan to Pennsylvania and engaged in the production of nonsparking tools and other beryllium-copper castings but continued to sell a major portion of its output in the form of master alloys to the American Brass Co. and the Riverside Metal Co. for remelting and fabrication. Under the new set-up the Beryllium Corporation of Pennsylvania, however, will be in a position to supply all kinds of beryllium and copper

[1] Chemistry and Industry (London), Elements Still Missing: Vol. 57, No. 32, August 6, 1938, p. 740.

Digitized by Google

products, including sheet, strips, wire, and tubing as well as castings, finished alloy, ingots, and master alloys. Inasmuch as it also will produce sheet bars and billets from the molten alloys, the new policy may result in other fabricators undertaking the manufacture of some of these products, thereby broadening the market. The equipment of the new fabricating plant is much heavier than that hitherto employed for forming the hardest copper alloys, and all operations from the purchase of the ore to the marketing of the products to the ultimate consumer will be under the technical control of the one company. The capacity of the plant exceeds anticipated needs at present and can be increased readily as required.

Price has always been a deterrent to more rapid expansion in the use of beryllium. The price of the beryllium content of master alloys was reduced a year ago from $30 to $23 a pound of Be content, but the base price of finished beryllium-copper products (about 2.25 percent Be) had to be increased from 89 cents to $1.12 a pound owing to the difficulties of fabrication. According to information furnished to the Bureau of Mines it is expected that this price can soon be reduced. To meet the demand for a material intermediate in physical properties between standard beryllium copper and phosphor bronze an entirely new group of alloys is being offered. One series contains 0.4 to 0.5 percent Be, 2 or 3 percent cobalt, and the rest copper; another is similar, except that chromium replaces cobalt; and still another comprises beryllium-nickel alloys that heretofore have not been manufactured commercially in the United States.

Possibly the most significant development in the beryllium industry during 1938 was the interest in the wider use of the element in munitions, more specifically in vital parts of airplane engines. Of interest also is the employment of beryllium or, better, an 80-percent ferroberyllium, for cementing steel. Beryllium dissolves readily in gamma iron, and by a suitable technique a maximum penetration of 20 to 25 millimeters can be obtained—with the case-hardened surface showing a hardness of over 1,000 Brinell.[2] Beryllium oxide films may be used to prevent tarnish on silver, although preliminary reports [3] indicate that aluminum may be as satisfactory, and of course it is much cheaper.

Among alloys in practical use are nickel with 2.5 percent Be, which hardens to 600 Brinell after quenching from 1,100° C. and drawing at 400° to 500° C., and 18-carat gold, which beryllium hardens to 300 Brinell. Steel with 36 percent nickel and 1 percent beryllium is rustless and machinable, but like Invar it does not expand or contract when heated. Beryllium forms a eutectic with iron at 9.2 percent Be and 1,150° C., and this alloy can be refined in grain by heat treatment. Tin-beryllium alloys containing 0.2 percent Be are 20 percent less ductile than pure tin but are slightly harder and have improved bending strength. When the proportion of beryllium is increased primary crystals of beryllium form in a ground mass containing only a few tenths of 1 percent Be. Beryllium additions to aluminum-magnesium alloys prevent loss of Mg by oxidation during melting, prevent surface defects on castings, and inhibit discoloration during heat treatment. They tend, likewise, to promote coarser structure,

[2] Kontorovich, I. E., Diffusion of Beryllium in Iron Alloys: Metallurgy, vol. 12, No. 6, 1937, pp. 21-30; Chem. Abs. vol. 32, No. 14, July 1938, p. 5356.

Digitized by Google

increasing the time of heat treatment and decreasing mechanical properties, but this disadvantage is neutralized by adding a little titanium. Only 0.02 percent Be is required in these alloys, and it is obtained from a master alloy containing about 90 percent Be and 7 to 12 percent Mg made by adding the double fluoride of these metals to the surface of an aluminum bath at about 1,350° F.[4]

The search for uses of other alloys and even of the metal itself continues unabated, but practical sales effort in the United States hitherto has been focused mainly on expanding the demand for beryllium-hardened copper in electrical devices and small machines. This alloy, which is soft and ductile before heat treatment and easily fabricated, can be made hard and high in elastic properties by simple one-stage treatment. Its exceptional resistance to fatigue and good electrical conductivity make it a valuable material for flat and coil springs. To illustrate the remarkable life of beryllium copper, one manufacturer reports that vibrator springs, heavily stressed 230 times per second and subjected to severe temperature changes, exhibited no measurable alteration in physical or electrical performance after 2 billion vibrations.

About 1 ton of beryllium worth 3,000 francs per kilogram (about $40 a pound) is now being produced annually in France. A leading electrical company makes it by electrolysis in a fluoride bath from beryl obtained near Limoges and Autun, supplemented by supplies from Madagascar. Italy, Japan, and possibly other countries are credited with small or occasional outputs, but the United States and Germany produce the bulk of the world beryllium supply in the form of alloys.

Beryl occurrences have been reported in various parts of the United States, but few mines outside of the Black Hills, S. Dak., have produced as much as a carload, and most of the domestic production has been obtained as a byproduct of feldspar, lithium, or rare-metal ore mining. No statistics of domestic output are available. A substantial part of domestic consumption in recent years has been supplied by imports, which in 1938 amounted to 146 short tons valued at $5,990, all from British India and Argentina excepting a 10-ton lot from the Union of South Africa. In 1937 imports were 182 tons valued at $8,031, and in 1936 they were 162 tons valued at $6,681.

Deposits of beryl in U. S. S. R. have recently been reviewed.[5] The most important deposit, which also yields emeralds, is some 70 kilometers from Sverdlovak, in the Urals; the beryl is associated with talc, mica, chlorite, and actinolite schists. In a recent report, which confirms previous reports, Hungarian bauxites are found [6] to contain only 0.005 to 0.01 percent BeO, far too little to encourage hopes of industrial recovery of the beryllium.

More beryl is being offered than can be consumed at present demand levels, and the price is still quotable at $30 a ton f. o. b. mines for 10- to 12-percent ore and up to $55 a ton delivered at consuming plants for higher grades. These figures correspond to an ore cost of approximately $1.25 a pound of recovered beryllium metal, which could be increased substantially if necessary to stimulate mining and still per-

Digitized by Google

mit the metal to be made at well under $5 a pound. Many people have labored under the delusion that beryllium cannot be sold at less than $23 a pound, even in its master alloys, because conversion costs are excessively high; this is not true. Suitable methods of reducing the metal from its ores have already been worked out, and they are not inherently expensive. On the other hand, very large sums have been spent upon research, educational campaigns, patents, and other expenses incident to the development of a new metal, and the burden of these expenses has had to be borne by a relatively small volume of actual sales. It is confidently asserted that $10 a pound is an early possibility, provided the scale of operations can be substantially increased. It is somewhat less certain what can be done about lowering prices to the ultimate consumer because less is known as to the cost of manipulating the alloys; however, a base price of 75 cents for the standard 2.25-percent copper alloy is mentioned tentatively as being in sight, and eventual reduction to not more than double the cost of phosphor bronze seems likely.

## CALCIUM

Calcium is recognized as a coming metal and already has begun to find industrial applications, especially as a scavenger and alloying element. The United States is the largest user, but France and Germany are the leading producers. Imports of calcium in 1938, almost all from France, amounted to 41,299 pounds valued at $16,144, as against 23,767 pounds and $10,087 in 1937. Imports of calcium alloys, however, declined, those of calcium silicide (a steel-making alloy imported chiefly from Norway but also from France) being reduced to 701 short tons valued at $77,003, from 1,876 tons and $205,173 in 1937.

The present status of the industry has been reviewed recently and comprehensively in a French paper.[7] Owing to its relatively high cost (65 cents to $1.50 a pound), calcium has not found general use in steel making, but its use for deoxidizing stainless and special-alloy steels increased in 1938. Either the metal or the hydride is employed as a reducing agent in the production of sundry rare metals, such as titanium, vanadium, and uranium.

## COLUMBIUM AND TANTALUM

World production of tantalum and columbium ores rose from about 6 tons in 1930 to 200 tons in 1934 and probably to about 750 tons annually in 1937 and 1938. This expansion is due mostly to the increased output of columbite for use chiefly in making ferrocolumbium. Columbium-bearing stainless steels successfully withstand high temperature, are more weldable than ordinary stainless steel, and are more resistant to corrosion. In 4- to 6-percent chromium steel, columbium reduces air hardening and stabilizes the physical properties, especially impact strength. The metal itself is very similar in general properties to tantalum, but when gas-free it is more ductile and can be more easily worked into wire and sheets. According to Kreuchen [8] the melting point of columbium is 2,500° C., more

Digitized by Google

than 350° under that of tantalum. It resists gases as well as tantalum up to a temperature of 300° C. but burns in air at about 400° C. At high temperatures columbium hydride, a glass-hard material, is formed. Columbium shows good resistance to corrosion, except by hydrofluoric acid, concentrated sulfuric acid, concentrated hydrochloric acid, and strong alkalies; in virtually every instance chemical attack seems to be due to the action of hydrogen and the formation of the brittle hydride.

The great affinity of tantalum and columbium for all common gases has led to an extensive use of both metals in the vacuum-tube industry. The remarkable resistance to corrosion of tantalum explains its use in chemical-plant equipment, and the great hardness of carbides of tantalum and columbium has led to their increasing use in carbide compositions. One of the newer applications for tantalum is in a complete absorption system for producing hydrochloric acid. Tantaloy, an extremely hard tantalum alloy, is nonmachinable but is supplied in bars, rods, and other simple shapes for welding upon base metals. It is used principally in the chemical industries for spray nozzles and wear-resisting surfaces but is recommended also for general abrasion- and corrosion-resisting service, as well as for use in cutting tools, the purpose for which it was originally designed. Balke has covered the uses of these metals in some detail.[9] In a later paper [10] he describes methods for producing ductile bars of these metals by powder metallurgy. Tantalum carbide tool compositions have been discussed by McKenna.[11]

The world's tantalite has come principally from Western Australia; the Wodgina property in the Pilbarra field has produced 20 or 30 tons yearly from alluvial material below a pegmatite outcrop. The concentrates carry less than 10 percent $Cb_2O_5$ and average approximately 65 percent $Ta_2O_5$. Columbite recently has been produced, principally in connection with tin placer mining, in Nigeria, which reported shipments of 707 tons in 1937 and reserves approximating 10,000 tons.[12] The leading producer in 1937 was Jantar-Nigeria, which shipped 410 tons to the United States; a half-dozen other companies made shipments to England. During the last year or two the Belgian Congo has been described as a possible producer of both tantalum and columbium ores. Mathieu[13] expects this colony to become an important source of these minerals. The average tantalum content of the Belgian Congo deposits seems to be higher than that of the Nigerian product but lower than that of the product of the Pilbarra field in Western Australia. Tantalite has been found in Australia also at Grant's Creek 17 miles west of Forsyth, associated with albite in pegmatite; the importance of the occurrences in this area has not yet been determined.[14] In 1938 a production of 7 tons of tantalite valued at £1,742 was reported in Uganda.

In the United States, the main supply of tantalum ore has been imported from Australia and raw material for making ferrocolumbium

from Nigeria. In 1938 the imports of tantalite rose to 41,706 pounds valued at $80,092, compared with 20,897 pounds valued at $40,742 in 1937; the imports of columbite declined to 645,141 pounds valued at $228,078 from 922,654 pounds and $306,086 in 1937.

However, small lots of tantalum-bearing ores (chiefly columbo-tantalite) have come from New Mexico, Wyoming, Colorado, North Carolina, and Virginia and have also been reported in California, Connecticut, Maine, and South Carolina.[15] At present, the only important domestic sources of ore used for making tantalum metal are the deposits in the Black Hills of South Dakota, although there is a small output from Amelia, Va.

*Shipments of tantalum-bearing ores in the United States, 1934–38*

| Year | Pounds | Value | Year | Pounds | Value |
|---|---|---|---|---|---|
| 1934 | 2,425 | $968 | 1937 | 16,307 | $13,317 |
| 1935 | 7,681 | 4,521 | 1938 | 36,189 | 35,127 |
| 1936 | | | | | |

The first real interest in commercial production of tantalum ores other than as a byproduct was in 1927, when some good showings were opened up while a road was being graded through the east side of a pegmatite dike in connection with construction of a 150-ton concentrator for the Black Hills Tin Co. After the production of several tons of concentrates containing 38.7 to 57.0 percent $Ta_2O_5$ in 1928 and 1929, operations were discontinued until 1936 when amblygonite was identified on the dumps, which accordingly were worked over for lithium ores. The Fansteel Mining Co., a wholly owned subsidiary of the Fansteel Metallurgical Corporation, obtained a lease on the property in February 1937, sunk a 60-foot shaft, and drifted southward under the ore, which is mined by open pit, dropped through raises, and eventually hoisted from the shaft. Approximately half the tonnage mined is sorted out as waste, the remainder going to a small mill, where it is crushed to minus 8-mesh and tabled. The geology of the occurrence has been discussed by Hess and Bryan.[16]

## INDIUM

No metal costing almost $30 an ounce can hope to enter the industrial field unchallenged, but the systematic search for uses for indium seems likely to bear fruit in the relatively near future. In a comprehensive review of available information on indium published in 1938,[17] Grasselli Chemical Co. technologists report that it is doubtful whether any of the numerous suggested uses have yet been adopted on a commercial scale. The most promising outlet, they believe, is in precious-metal alloys for jewelry and dental work, in which indium increases resistance to corrosion. Silver-indium alloys containing 1 to 25 percent indium have been developed for plating silverware to prevent tarnishing, and a dental amalgam base (patented) containing

Digitized by Google

95 percent mercury and 5 percent indium is claimed to improve the mechanical properties of the filling. Indium further lowers the melting point of low-melting alloys; addition of 18 percent indium to Wood's metal yields a metal that is fluid at 46.5° C. Other potential uses include bearing metals (especially those utilizing the new technique of plating on and diffusion into cadmium alloys, as described by Smart [18]), mirrors, medicine, and glass making. Indium oxide and sulfur compounds impart light-yellow to dark-yellow amber colors to glass, and only 0.05 percent indium oxide is said to give a beautiful yellow glass. Binary indium-tin alloys have been investigated recently; they show higher resistance to both fatigue and corrosion, yet are soft and ductile. Other alloys investigated previously include those with copper, gallium, lead, lithium, silver, sodium, tellurium, and zinc, respectively. The search for commercial outlets is still being pushed vigorously because potential supplies are relatively large.

With the introduction of various wet methods of extracting zinc, indium and certain other rare metals have become readily available if needed. Indium and sundry associated metals are extracted from the complex waste mud from these processes with hot dilute sulfuric acid and reprecipitated by treating the solution with zinc. The resulting sponge, which contains not only indium but also cadmium and a little lead, nickel, tin, and copper, is filtered off and leached first with not quite enough hot dilute acid to dissolve the cadmium. Further leaching of the remaining sponge dissolves other metals, and after lead sulfate and other insoluble matter have been filtered out this second solution is treated with an excess of ammonia thereby precipitating indium hydroxide, which can be separated, washed, and eventually ignited to trioxide. Metallic indium of 97 to 98.5 percent purity is made directly from this impure trioxide by an electrolytic method and can be purified further if required.

## MESOTHORIUM

Mesothorium is used medicinally in the treatment of cancer and skin diseases and in luminous paints as a radium substitute. Actually almost all material so designated contains more radium than mesothorium, but as the latter is approximately 30 times as radioactive the product is sold as mesothorium. There are no official statistics of domestic production or exports. Imports are classified as "radioactive substitutes" and shown in value only. Ordinarily they are not very important, but in 1938 they jumped to $5,746 compared with $711 in 1937. The bulk of the small domestic consumption is supplied by domestic sources. As most users require a National Bureau of Standards certificate before they purchase material, the following record of such tests affords a fair measure of the output and demand in the United States.

Mesothorium is produced in this country from the residues of monazite sand after thorium and cerium have been extracted for use in gas mantles. The extraction process is very much like that for radium. The residues are digested in hot concentrated sulfuric acid and treated with barium salts to form a precipitate of mesothorium-barium sulfate, which is filtered, redissolved by treatment with sodium carbonates, and purified by a long series of fractional crystallizations.

| 1933 | 8 | 136 | | | |

The only known foreign producer is Deutsche Gasglublicht Auergesellschaft, Frankfort on the Main, Germany, a leading gas-mantle manufacturer.

## RADIUM AND URANIUM

Early in 1939 it was reported that a marketing agreement had been concluded between Union Minière du Haut Katanga (operating in the Belgian Congo) and Eldorado Gold Mines, Ltd. (Canada), for marketing radium, whereby the former will supply 60 percent and the latter 40 percent of world requirements. Some years ago an agreement was in effect between the Belgian company and the Czechslovak Government, but in recent reports no mention is made of outside production. The Joachimsthal (Jachymov) deposits in the Ore Mountains lie in territory ceded to Germany; they are of interest not only because they normally supply 1 to 3 grams of radium a year but also because they supplied the pitchblende that Mme. Curie employed in all her early work. Small quantities of radium ores are produced in the United States, the U. S. S. R., and Portugal.

Canada entered the ranks of radium producers with an output of 3.025 mg. in 1933 and became an important factor when its output rose to 15.54135 grams in 1936. By the middle of 1938 its operating rate had been stepped up to 1 gram of radium salts weekly, with a projected capacity of 85 grams yearly. The estimated output for the year was 70 grams compared to the 1937 total of 23.77014 grams. According to reports by the Dominion Bureau of Statistics (Ottawa), 25,486 tons of ore were hoisted during 1937 at the Eldorado mine, which yielded a total of 674.5 tons of concentrates and cobbed ore, comprising 475.3 tons of pitchblende-silver, 193.3 tons of silver-copper (flotation), and 5.9 tons of cobalt (cobbed) concentrates. Receipts of pitchblende concentrates at the company Port Hope (Ontario) refinery were 339 tons; but only 294 tons, yielding 302 tons of roasted ore, were put through the roasting and milling plant in 1937, and of the latter only 290 tons entered into the chemical treatment. Recovery of both radium and uranium was about 90 percent and of silver about 96 percent. It is stated that about 5.2 tons of uranium salts are recovered per gram of radium. Silver is marketed as silver sulfide to refineries in the United States, and the total value of all products was reported at $850,000 in 1937. This figure includes the value of radioactive lead, which was recovered in the form of lead sulfate to meet an industrial demand for radium D; the ore contains about 5 percent such lead. The company recently has offered radioactive lead oxide made from this lead, which is required for scientific and research purposes.

Digitized by Google

Eldorado Gold Mines stock sold at $1.38 to $3.25 per share in 1938, compared with a maximum of $8.10 in 1933 when the property was still in the development stage. Ore reserves valued at $5,956,482 on December 1, 1937, were marked up to $7,000,000 in June 1938. The company report states that as of October 1, 1938, unfilled orders for radium exceeded $700,000, and sales during the first 9 months totaled $1,007,539, about 100 percent ahead of 1937. Mill costs at Port Hope have been cut 20 percent, and mining and concentrating costs at Great Bear Lake also have been reduced, whereas prices of uranium and uranium products have increased.

A few other occurrences of pitchblende have been reported in Canada. The Consolidated Mining & Smelting Co. did considerable development on claims near Common Lake, adjoining the Eldorado property to the northeast, but suspended its work in June 1936. Parcels of ore have been shipped from discoveries made several years ago at Beaverlodge and Hardisty Lakes about 100 miles to the south, and pitchblende was discovered in 1935 near Goldfields, on Lake Athabasca, where it occurs in narrow veinlets that also carry gold. Canada Radium Mines conducted underground exploration for radioactive minerals in pegmatite at Cheddar near Wilberforce in northern Hastings County, Ontario, but suspended this work in 1937. The Bear Exploration & Radium, Ltd., following much surface and underground development, made a test shipment of silver ore as early as 1934 from its property at Cameron Bay, Great Bear Lake. In 1938 this company was reorganized and refinanced by the Eldorado Mines, Ltd., and began producing concentrates.

Radium is sold in grades according to the percentage purity of the salt. The usual purity is 98 percent. For domestic transactions radium is compared at the National Bureau of Standards with the National Radium Standard, a duplicate of the international standard prepared by Mme. Curie and deposited in Paris. Other duplicates are found in leading capitals throughout the world. The measurement involves comparison of the electrical energy carried by the X-rays, and certificates are issued. During 1938 the National Bureau of Standards, under the supervision of Dr. L. F. Curtiss, tested 1,280 radium preparations with a radium content of 10.5 grams compared with 1,703 preparations containing 9 grams in 1937.

Imports of radium salts into the United States rose in 1938 to an all-time record of 38.75 grams valued at $787,025, compared with 15.29 grams valued at $377,659 in 1937. The previous record was only 21.97 grams in 1934, but owing to the somewhat higher prices then prevailing the valuation in that year was $1,082,462. Imports of uranium oxides and salts never exceeded 20,000 pounds a year until 1926 but have been increasing almost steadily to a peak of 341,040 pounds valued at $374,110 in 1936. After dropping to 203,473 pounds with a value of $258,417 in 1937, they advanced to a new high record of 376,708 pounds valued at $520,540 in 1938.

Radium salts are marketed either in the form of implants in gold or platinum needles containing 1 to 12½ mg. or in sealed tubes of glass, silver, or platinum containing 10 to 100 mg. Radon, or emanation, ordinarily is sold in gold implants or "seeds" 5 to 7 mm. long and 0.5 mm. in diameter. An outer case of lead is customarily employed to decrease danger of handling. Radium for radiograph testing of metals may be placed in small drum-shaped silver containers holding 100 mg.

Digitized by Google

A recent proposal is to use tungsten shields which, owing to their greater density, may be more effective than those of other metals, including lead.

In some hospitals the radium is stored in solution, and only radon is collected and used.

"Radium Protection" (National Bureau of Standards Handbook H 23) is a manual of recommended precautions to be observed by those whose work involves handling of this dangerous element.

Radium is often handled in such minute quantities that occasional loss is inevitable—100 mg., the usual dose for treating cancer, would barely cover the head of a pin. Because it is worth roughly 18,000 times its weight in pure gold and especially because it menaces the lives of those who may unwittingly come into contact with its destructive rays, ingenious devices have been developed to recover it. About 20 of these devices—most of them home-made affairs using gold-leaf electroscopes—are in use in the United States, and of 107 reported losses 59 complete recoveries and 11 partial recoveries of radium have been made, according to an interesting article by Taft.[19]

The price of radium, after reaching $135 a milligram during the World War, was cut to $70 in 1923 and to $50 in 1930. The quotation since August 1936 has been nominally $40. The principal use of radium is therapeutic, its chief application being in the treatment of cancer, although radium therapy is employed also for the treatment of sundry dermatological conditions and other diseases. The principal industrial use has been in luminous paints for watch dials, instrument scales, switches, press buttons, signboards, and signals. A more recent development is the use of radium by physical metallurgists for inspecting metal castings for flaws. Radium is much easier to handle than X-rays and is said to give even better results.

*Radium and uranium content of carnotite ores produced in the United States, 1934–38*

| Year | Carnotite ores (short tons) | Radium content (milligrams) | Uranium content (pounds) | Year | Carnotite ores (short tons) | Radium content (milligrams) | Uranium content (pounds) |
|---|---|---|---|---|---|---|---|
| 1934 | 254 | 1,007 | 6,661 | 1937 | 1,708 | 3,141 | 20,764 |
| 1935 | 1,145 | 3,329 | 22,009 | 1938 | 4,290 | 7,821 | 51,705 |
| 1936 | 1,439 | 2,716 | 17,961 | | | | |

Notwithstanding its high price, uranium, mother of radium, is used extensively in ceramics.[20] A stain of sodium uranate, alumina, and silica is used in strongly fired glazes to produce ivory to yellow shades, and in low-fired lead glazes a tomato-red color is obtained by the addition of 15 to 20 percent sodium uranate. Uranium oxide is used in glazed pottery to produce luster or iridescence, coloring the ware greenish yellow, and in glass to yield a wine-yellow color in transmitted light and a greenish-yellow fluorescence in reflected light.

After failing to justify its high price as a ferro-alloying element, uranium is now being added to copper. R. R. Mallory & Co., Inc., Indianapolis, Ind., offers a hard ternary alloy containing copper and uranium which, it is claimed, affords improved performance and

Digitized by Google

longer life to current-carrying or heat-carrying members of electrical machinery. Besides its high electric and thermal conductivity, this new alloy is unusually resistant to corrosion by a wide variety of gases and liquids, according to Business Week (December 24, 1938, p. 27).

At the close of 1938 sodium uranate, $Na_2UO_4$, was quoted at $1.75 to $1.80 per pound for either the yellow or orange variety; uranium oxide, 96 percent $U_2O_6$, in 100-pound lots at $2.65 to $2.75 a pound for the black and $1.75 to $1.80 for the yellow or orange product.

## RARE EARTHS

The rare earths continue to command the attention of numerous research workers, although commercial developments are impeded by their high price. Paradoxically, the rare-earth metals are not extremely rare in nature. But they are difficult to separate, and many of their potential uses can be satisfied by cheaper elements. The oxides of cerium are used in ceramics and special glasses. A good résumé of the use of rare earths in the glass industry was published [21] recently, and another paper [22] calls attention to the availability of lanthanum as a byproduct of recovering thoria and ceria from monazite and its potential applications in the ceramic and glass industries, for weighting silk, as a catalyst, and as a constituent of alloys. Ceric oxide is one of the best opacifiers [23] for enamels, yet it is seldom used even in Europe.

Neodymium and praseodymium [24] occur in all cerium minerals in a ratio of at least two parts neodymium to one part praseodymium. Recently neodymium (which stains glass violet) has been applied successfully as a physical decolorizer for glass. Didymium, a mixture of neodymium and praseodymium, gives a neutral-gray glass.

As an illustration of the wide distribution of the rare earths, the Bureau of Chemistry and Soils in cooperation with the National Bureau of Standards has recently identified substantial traces of rare-earth metals in the ashes of many plants. The rare-earth concentrate from hickory leaves grown in a pegmatite vein amounted to 0.2 percent of the dry weight of the leaf.

The Glass Industry (January 1939 issue) quoted cerium hydrate (100-pound drums and 600-pound barrels) at 60 cents a pound, neodymium oxalate (50-pound drums) at $3.50 a pound, and "rare-earth hydrate" at 30 cents (325-pound barrels) to 35 cents (100-pound drums) a pound.

## SELENIUM AND TELLURIUM

More and more selenium is being recovered from copper refining; and, as the use of selenium in glass no longer seems to be increasing, the search for new uses has been resumed. The demand for tellurium is still much less than that for selenium and only a fraction of the quantity that could be recovered if byproduct sources were fully utilized. Tellurium is used to increase the toughness and resistance

[21] Ctyroky, V., Importance of Rare Earths for the Glass Industry: Sklarske Rozhledy, vol. 15, 1938, pp. 23-33; Ceram. Abs., vol. 17, No. 8, August 1938, p. 274.

Digitized by Google

to abrasion of rubber hose and cable coverings. Increasing amounts of tellurium lead are being marketed, but this outlet is only a small one, as it takes only a few hundredths of 1 percent of tellurium to harden, toughen, and increase the corrosion resistance of ordinary lead. According to a report of the International Tin Research and Development Council (Pub. 81) tellurium also improves remarkably the work-hardening properties and creep strength of tin; in quantities up to 0.1 percent it improves somewhat the tensile strength and hardness. Industrial hazards from selenium and its toxicity are the subject of a recent Government report.[25] Further research indicates that the bad effects of selenium in soils have been greatly exaggerated.[26] In fact some plants seem to be stimulated by selenium, and a few may actually need it to thrive.[27]

Prices of selenium (black, powdered, 99.5 percent) remained virtually unchanged in 1938 at $1.75 to $1.85 a pound in New York but rose slightly to 7s. 3d. in London. Barium selenide, $BaSeO_3$, is quoted in domestic glass-trade journals at $1.40 to $1.60 a pound, while the quotation for the "commercial" grade (25 percent Se) remains at 85 cents. Sodium selenite, $Na_2SeO_3$, which is also used in glassmaking, is quoted at $1.50 to $1.65 a pound in 1938. New York quotations of $2 a pound for tellurium have remained unchanged for several years, and London trade journals continue to quote the metal at 7s.

*Production, sales, and imports of selenium and production and sales of tellurium in the United States, 1934–38*

| Year | Selenium | | | | Tellurium | |

## TITANIUM

Because of their great whitening and obliterating power, titanium pigments continue to be employed widely in paint, rubber, linoleum, leather, plastics, soap, printing inks, paper, textiles, and ceramics. In addition to the well-known white pigments an important rich-yellow pigment has recently been developed that contains chromium and antimony as well as titanium dioxide. Ilmenite, used chiefly for making titanium pigments and to a smaller extent for making ferro-alloys, is produced in the United States in Virginia, Arkansas, and California, but the main supply is imported from British India, by far the world's largest producer. Rutile is produced in this country, both for domestic consumption and for export and is also imported

from Brazil and Australia. Deposits are being opened up in various other countries. The principal uses of rutile are in welding-rod coatings and ceramics; the former recently has become the most important outlet, consuming as much as 1,200 to 2,500 tons a year.[28]

The Bureau of Mines is not at liberty to publish figures of domestic production of ilmenite and rutile. Imports of rutile declined to 130 short tons valued at $26,533 in 1938 compared with 665 tons and a value of $67,643 in 1937. Those of ilmenite continued their phenomenal expansion, reaching 201,545 long tons valued at $1,018,430 compared with the previous record of 153,993 tons valued at $770,757 in 1937.

The rapid growth of the titanium industry and the increasing variety of uses for the element in its sundry products have been reviewed in previous volumes of Minerals Yearbook and are not repeated in this chapter. During 1938 ilmenite was discovered in Natal, payable quantities being reported in sand dredged from Durban Bay. In southern Egypt the Hamata Mining Co., already engaged in mining manganese, installed equipment for producing ilmenite. Rutile, which has been mined sporadically in French Cameroons in Africa, may be mined more systematically following the gradual acquisition of mining rights in the numerous areas. Rutile has been produced extensively in Australia from beach sands at Byron Bay and elsewhere in New South Wales where it occurs with zircon. Deposits of this mineral in South Australia were visited in 1937 by the Government Inspector of Mines, who cautioned against premature expansion of the existing pilot plant which can treat a maximum of 2 tons of crushed ore, equivalent to about 180 pounds of 80 percent concentrate, daily.[29] In South Africa the property in Omaruru that produced over 16 tons of rutile from a high-grade deposit (4 to 20 percent $TiO_2$) was idle in 1938, having been optioned to an overseas firm according to a Government report. The Dominion Bureau of Statistics (Ottawa) reveals a sharp increase in production of titanium ore in Canada to 4,229 short tons valued at $26,432 in 1937, with a drop to 207 tons worth $1, 449 in 1938. The entire output was shipped from St. Urbain, Quebec, to ferro-alloy manufacturers. In France titanium, as well as vanadium and zircon, may be recoverable from "red mud" from bauxite refining.

A new titanium mineral, $FeTiO_3.Fe_3O_4.TiO_2$, is reported [30] from Nellore, India.

Engineering and Mining Journal quotations for titanium ore in 1938 were: Ilmenite, 45 to 55 percent $TiO_2$, f. o. b. Atlantic seaboard, $10 to $12 per gross ton according to grade and impurities; rutile, guaranteed minimum 94 percent concentrate, 10 cents per pound (nominal); 88 to 90 percent, $55 per ton, c. i. f. New York; ferro-carbon-titanium, $142.50 per short ton f. o. b. producer's plant. The price of titanium dioxide was reduced 1 cent at the end of the year to 14 and 14½ cents a pound (carloads). Phthalate-treated pigment was quoted at 22 to 22½ cents per pound with extras for smaller quantities.

## ZIRCONIUM

Australia, India, and Brazil still supply the bulk of the world's zircon, and Brazil is the only source of baddeleyite. Zircon sand is present in concentrates and black sands from California placer-gold mining. It was recovered in commercial quantities for the first time in 1937 in the sluice boxes of the Kaufield dredge, 2 miles east of Lincoln, Placer County, Calif. Exact figures are not available but this appears to be the first domestic production since 1927 when operations at Pablo Beach, Fla., ceased.

The rise to importance of zirconium during the last quarter of a century and the many uses of the metal and its compounds and alloys have been discussed in previous volumes of Minerals Yearbook and are covered more fully in recent papers published by the Foote Mineral Co.[31] An even more comprehensive review appeared in a foreign trade journal.[32]

According to Saklatwalla [33] copper containing 14 to 16 percent zirconium metal yields an alloy comparable to beryllium copper. A new alloy, Silvaz, containing 6 to 6.5 percent zirconium has been developed as a steel refiner. It also contains about 6 percent each aluminum and vanadium and about 40 percent silicon (balance iron). This alloy is claimed to produce better results in refining steel than separate additions of the respective alloys, particularly as to yield and Izod impact ductility. One new use for zircon sand is in the manufacture of molds for cast steel, and another is as an insulator in electric heating devices.

Zirconium metal is used in radio tubes (wire) and rayon spinneret cups (sheet). Zirconium-silicon and zirconium-ferrosilicon alloys are used in steel making, whereas the powdered metal goes into flashlight mixtures and ammunition primers. Even in the aggregate the requirements for such purposes are small, and the bulk of tonnage is in the form of compounds for use in ceramics and welding-rod coatings. The main consumption is in enamel and glaze frits which employ not only zirconium oxide but also zircon and sodium zirconium silicate.

Engineering and Mining Journal quotations during 1938 were nominal: Zircon ore, 55 percent $ZrO_2$, f. o. b. Atlantic seaboard, carload lots, $55; 5-ton lots, $60 per short ton; crude granular zircon, $70 f. o. b. Suspension Bridge, New York, milled, $90.

| Statistics of lignite and hard coal outside of Pennsylvania | 829 |

The year 1938 proved to be an eventful one for the coal industry. The sharp drop in the demand for industrial coal resulting from the general recession in business was accentuated by the extraordinarily mild weather that reduced consumption for heating purposes. In addition, competitive fuels continued to make inroads into the diminishing coal market.

A measurable degree of relief was in prospect at the end of the year through the work of the National Bituminous Coal Commission. On February 25 this agency was forced to withdraw the marketing rules and regulations and schedules of minimum prices that it had established late in 1937. During the remainder of the year the Commission proceeded with the task of building a minimum price structure that would comply in detail with requirements of the law. Although

[1] The collection of production statistics of the bituminous-coal industry previously conducted by the Bureau of Mines was transferred to the National Bituminous Coal Commission July 1, 1937. The cooperation of the Coal Commission in contributing this chapter to Minerals Yearbook to maintain the continuity of the bituminous-coal series is gratefully acknowledged.

Data for 1938 are preliminary; detailed statistics with final revisions will be released later. Data for 1937 are final.

Digitized by Google

the goal seemed to be in sight at the end of the year no one would venture to predict just when the new prices would be put into effect.

*Production.*—The output of soft coal in 1938 was 344,630,000 tons, a 23-percent drop below 1937. During the first 6 months of 1938 production averaged more than 30 percent below the comparable period of 1937. Although the coal industry made substantial gains along with general business during the latter half of the year, the total output for the year was only 11 percent above the record low of 1932 and 36 percent below the 534,989,000 tons of 1929. (See figs. 1, 2, and 4.)

*Imports and exports.*—Exports of bituminous coal fell from 13,145,000 tons in 1937 to 10,490,000 in 1938, a net drop of 20 percent. At the same time imports, which are relatively insignificant, declined 7 percent from 258,000 tons in 1937 to 241,000 in 1938. As in the past, virtually all these imports and more than 90 percent of the exports resulted from trade with Canada. (See fig. 9.)

*Changes in stocks.*—Over 6 million tons of the coal consumed in 1938 represented net withdrawals from consumer stocks. The

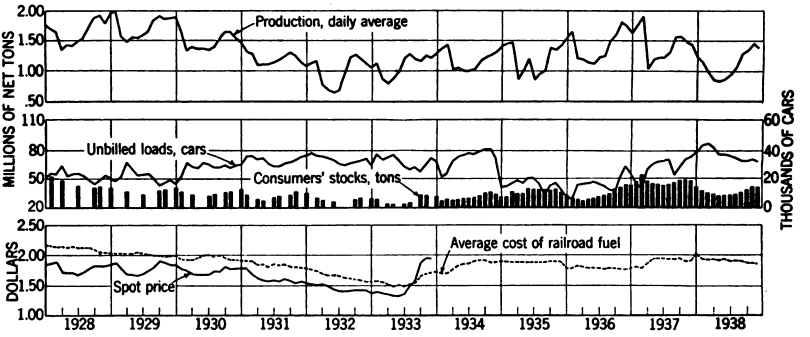

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal, 1928-38.

reserve supply of coal in the hands of industrial consumers and retail coal yards fell from a total of 47,074,000 tons at the beginning of the year to 40,720,000 tons at the close. Between the same periods stocks on the upper Lake docks declined 385,000 tons, and unbilled coal in cars at the mines or classification yards fell 174,000 tons. Although these stocks were consistently lower in 1938 than in 1937, in terms of day's supply they constituted a more adequate reserve, since consumption requirements fell even more sharply than stocks. (See fig. 1 and table 33.)

*Consumption.*—After allowances have been made for foreign trade and changes in consumers' stocks the total consumption of bituminous coal in 1938 amounted to 340,735,000 tons, a decline of 87,762,000 from 1937. Each of the more important classes of consumers shared the reduction, which ranged from 72 percent for beehive coke ovens to 10 percent for electric power utilities. The effect of the decline in industrial consumption was augmented by the weather, since 1938 was one of the warmest years on record. (See fig. 3 and table 4.)

*Distribution.*—Shipments of bituminous coal during 1938 dropped sharply below the 1937 level in each of the primary channels of

Digitized by Google

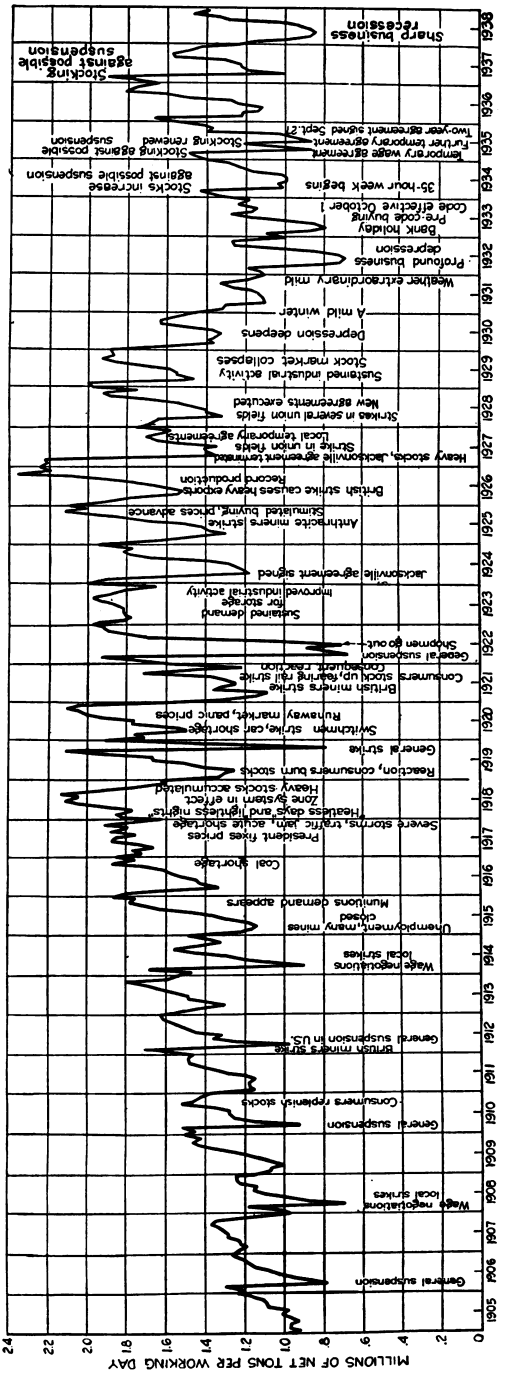

FIGURE 2.—Average production of bituminous coal per working day in each month, 1905–38.

Digitized by Google

distribution. Changes in the monthly volume of the more important movements are shown in figure 4.

*Freight rates.*—The average railroad freight charge per net ton of revenue bituminous coal amounted to $2.27 in 1938. The 10-cent-a-

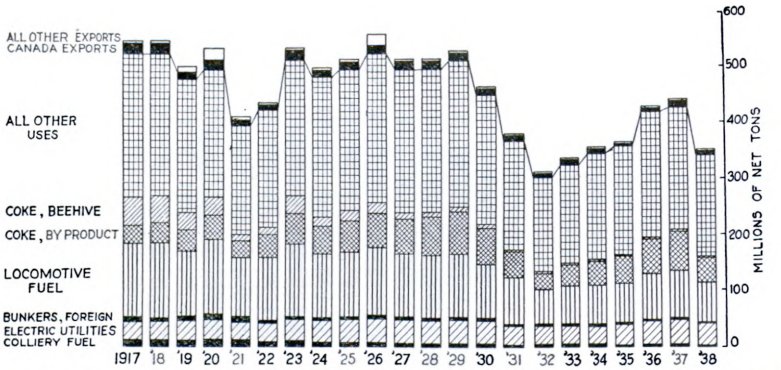

FIGURE 3.—Tonnage of bituminous coal absorbed by the principal branches of consumption, 1917–38.

ton advance over the 1937 average was a result of the new schedule of rates authorized by the Interstate Commerce Commission in Ex Parte 115. The new rates became effective on November 15, 1937, and provided for increases of approximately 9 cents per net ton east

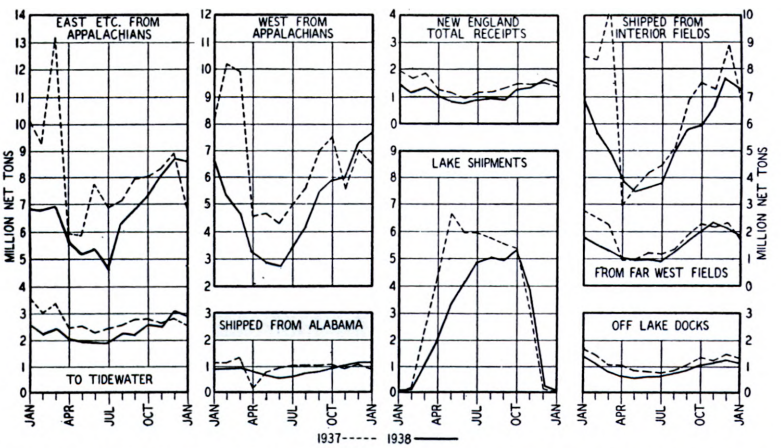

FIGURE 4.—Monthly movement of bituminous coal in the major channels of distribution, 1937–38.

of the Mississippi and 13 cents in the West. The increases ranged from 3 to 10 cents per net ton in eastern territory and from 3 to 15 cents in western, the amount depending on the basic rates.

*Trend of prices.*—During the first 2 months of the year prices of bituminous coal were supported by the schedules of minimum prices

Digitized by Google

issued by the National Bituminous Coal Commission. After these prices were withdrawn on February 25 the market quotations slumped sharply. Prices of screenings and slack, which depend very largely on industrial demand, showed the greatest weakness.

Spot market quotations indicate that producers averaged less per ton for their coal in 1938 than in 1937. On the other hand, the Bureau of Labor Statistics series of wholesale prices, f. o. b. destination, show a slight increase for 1938 considering the year as a whole. The divergent movement of these series is explained by the advance of 10 cents a ton between the 2 years in the average cost of transporting bituminous coal by rail. This increase in freight rates more than offsets the reduction in the f. o. b. mine price of coal and raised the delivered price above the 1937 level.

*Mechanization.*—On the basis of data available early in 1939 Coal Age [2] estimated that "25 percent of the deep-mined output was handled by some type of loading equipment." This represents a continuation of the sharp advance in mechanical loading from 16 percent in 1936 to 20 percent in 1937.

Sales of mechanical loading equipment for use in bituminous-coal mines declined in 1938, but at a rate considerably less than the drop in production. Although the output of bituminous coal fell 23 percent the reduction in sales of loading equipment was 17 percent for mobile loaders and only 10 percent for conveyors. Reports from 29 manufacturers show sales of 241 mobile loaders for the current year as against 292 in 1937 and 344 in the peak year of 1936. Conveyor sales totaled 749 in 1938 compared with 835 in 1937 and 682 in 1936.

Details regarding mechanization and equipment in 1938 are given in a supplement to Weekly Coal Report 1127 of the National Bituminous Coal Commission, entitled "Sales of Mechanical Loading Equipment for Use in Coal Mines in 1938," by L. N. Plein, J. J. Gallagher, M. van Siclen, and F. G. Tryon. Summary articles covering the same subject were published in the February 1939 issues of Coal Age and the Mining Congress Journal. (See also fig. 7 and tables 24 and 25.)

*Stripping operations.*—The volume of bituminous coal produced by stripping established a new record in 1937 when 31,750,853 tons were reported—a 13-percent increase over the output in 1936, when stripping operations produced a total of 28,125,857 tons. Although the proportion of strip coal continued to rise in 1938 there was considerable reduction in the total volume produced by this type of operation owing to the general drop in industrial demand.

*Mechanical cleaning.*—Over 61 million tons of bituminous coal were mechanically cleaned in 1936, and preliminary estimates indicate that the amount rose to about 65 million in 1937. Construction of new cleaning plants in 1937 and 1938 added materially to the capacity of the industry to produce mechanically cleaned coal.

*Trend of employment.*—Estimates of the number of men employed at bituminous-coal mines in 1938 indicate a substantial drop from the 1937 figure of 491,864. Indexes compiled by the Bureau of Labor Statistics on the basis of a sample that includes more than half the workers in the industry, show a 12.7-percent drop in employment for

[2] Coal Age, February 1939, p. 28.

Digitized by Google

1938. Reports from the mining departments of six States with more than 70 percent of the bituminous-coal employees in the United States indicate an average decline of 10.6 percent for the same period. These data suggest an estimate of 435,000 employees for 1938.

In comparison with 1929, when the average number of men at bituminous-coal mines totaled 502,993, the 1938 figure represents a decrease of 68,000. The number of unemployed coal-mine workers probably exceeded this figure, however, since a considerable number attached to the industry were without jobs, even in 1929. Furthermore, if it had not been for share-the-work agreements the number of unemployed miners in 1938 probably would have been still greater. A partial solution for the unemployment problem, which became exceedingly acute during the depression period, was provided by the industry's reduction of hours for a normal workweek from 48 to 40 and later to 35.

Statistics of employment for bituminous-coal workers cannot be interpreted properly without considering the intermittent operations that characterize most coal mines. In 1937, for instance, the bituminous mines were operated an average of 193 days out of the 261 possible under the 5-day week of the union wage agreement. Consequently, a substantial part of the manpower on the rolls of the industry was idle throughout the year, the number depending on the market and the season.

*Trend of capacity.*—The potential full-time output of active mines in the bituminous-coal industry continued to increase between 1936 and 1937. The coal industry reached its peak capacity in 1923 when, on the basis of 308 operating days, the potential output was 970,000,000 tons. Subsequent liquidations forced the closing or abandonment of thousands of mines and reduced the indicated capacity to 622,000,000 tons in 1934. Increases since 1934 have raised the potential output on a 308-day basis to 710,000,000 tons in 1937.

One of the outstanding developments under the Bituminous Coal Code of the National Industrial Recovery Act was the adoption of a 5-day week for the industry. Under the 5-day week full-time operations are limited to approximately 261 days. The potential capacity of operating mines on a 261-day basis was 601,000,000 tons in 1937 compared with the total actual production of 445,531,449 tons.

*Trend of fuel efficiency.*—Technologic improvements in utilization of fuel since the World War have been responsible for an appreciable reduction in the demand for coal for industrial use. Although the effect tends to be cumulative it should be noted that the changes have been taking place at a much slower rate in recent years. Steam railroads reduced their coal consumption per 1,000 gross ton-miles of freight service from 117 pounds in 1937 to 115 in 1938. Between the same years electric public utility power plants managed to lower the number of pounds of coal per kilowatt-hour from 1.43 to 1.41, and steel companies cut 1.8 percent from the amount of coking coal required to produce a gross ton of pig iron.

It is evident also that savings in fuel are being effected by both domestic consumers and small industrial establishments. Increasing economy in the utilization of fuel, arising from improved heating equipment, has been supplemented by developments in insulation and building construction. Automatic stokers, weather stripping, and

Digitized by Google

insulating materials have combined to limit the aggregate demand of domestic and small industrial consumers, who comprise a large segment of the national market.

*Competition of oil and gas.*—Although the consumption of bituminous coal by electric power plants, railroads, and steamships combined dropped 16 percent below the 1937 level the competitive use of fuel oil by the same groups of consumers decreased only 9 percent. At the same time total sales of natural gas also fell 9 percent.

Relative changes in sales of mechanical stokers and oil burners afford a slightly more encouraging picture for the coal industry. Stoker sales declined only 4 percent between 1937 and 1938, while net orders for oil burners dropped 28 percent. In absolute numbers, however, oil-burner sales exceeded mechanical stoker sales by about 50 percent.

*Prospects for 1939.*—The low point of the 1938 recession in the coal market was reached in June. In July the barometers of general business, which had been falling since the autumn of 1937, began to rise again. Although coal prices remained depressed, production continued on the upgrade throughout the remainder of the year. By the end of 1938 the curve of weekly production had overtaken that in the corresponding period of 1937.

The improvement noted has continued into 1939. Consumption has exceeded that in the early months of 1938. Production records up to April 1, when mining operations were suspended in the Appalachian fields, indicate that output during the first quarter of the year was running 23 percent above that for the corresponding period of 1938.

*Statistical tables—1938.*—Tables 1 to 5 give a statistical record of the bituminous-coal industry in 1938, as indicated by available preliminary data. They also show comparative statistics for the indicated earlier years, including final figures for 1937. (See fig. 5.)

| Average number of days mines operated, days | 232 | 179 | 219 | 146 | 178 | 179 | 199 | 193 |
| Nominal length of established full-time week [5], hours | 51.6 | 48.4 | 48.5 | 48.6 | 40.0 and 35.1 | 35.1 | 35.1 | 35.1 |
| Capacity of active mines with existing labor force: | | | | | | | | |
| Per year of 308 days (full time before October 1933), net tons | 635,000,000 | 970,000,000 | 752,000,000 | 653,000,000 | 622,000,000 | 640,000,000 | 680,000,000 | 710,000,000 |
| Per year of 261 days (5-day week basis), do | 538,000,000 | 823,000,000 | 638,000,000 | 554,000,000 | 527,000,000 | 543,000,000 | 576,000,000 | 601,000,000 |
| Output per man per day [6], do | 3.61 | 4.47 | 4.85 | 5.22 | 4.40 | 4.50 | 4.62 | 4.69 |
| Output per man per year, do | 837 | 801 | 1,064 | 762 | 785 | 805 | 920 | 906 |
| Underground output cut by machine, percent | 50.7 | 68.3 | 78.4 | 84.1 | 84.1 | 84.2 | 84.8 | [4] |
| Underground output mechanically loaded, do | | 0.3 | 7.4 | 12.6 | 12.2 | 13.5 | 16.3 | 20.2 |
| Quantity mined by stripping, net tons | [7] 1,280,946 | 11,940,134 | 20,268,099 | 19,641,128 | 20,789,641 | 23,647,292 | 28,125,857 | 31,750,853 |
| Quantity cleaned by wet or pneumatic processes [8], do | 22,069,691 | 20,140,385 | 32,271,950 | 27,357,599 | 35,853,714 | 39,511,176 | 53,332,040 | [4] |

[1] The earliest year in which figures were collected in strictly comparable form was 1933, when commercial sales by truck and wagon were 15,462,739 tons.
[2] The total production differs from the sum of the items shown by the amount of the changes in inventory and of tonnage not accounted for in the distribution analysis.
[3] The increase in number of mines shown for 1934–37 over preceding years is due partly to more complete coverage of small trucking mines (producing over 1,000 tons a year). See Minerals Yearbook, 1936, pp. 561–564.
[4] Data not available.
[5] The figures represent the full-time week as reported by the operator, not the hours actually worked by the men.
[6] Affected by changes in length of working day.
[7] Figures for 1914, the year of earliest record.
[8] Exclusive of central washeries operated by consumers.

| From Alabama field | 19,569 | [3] 3.5 | 17,503 | [3] 3.3 | 11,771 | [3] 2.7 | 10,177 | [3] 3.0 |

[2] Excluding commercial sales by truck and wagon, except from upper Lake docks.
[3] Percent of total national shipments from all mines, all destinations.
[4] Less than 0.05 percent.
[5] Data not available.

## SOURCES OF DATA AND ACKNOWLEDGMENTS

Bituminous-coal production statistics for 1938 are preliminary estimates based on (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, (4) monthly production statements compiled by various local operators' associations, including the following: Central Pennsylvania Coal Producers Association, Georges Creek and Upper Potomac Coal Association, Coal Trade Association of Indiana, Hazard Coal Operators Association, Kanawha Coal Operators Association, Eastern Ohio Operators Association, North Dakota Board of Railroad Commissioners, Utah Coal Operators Association, Virginia Operators Association, West Kentucky Coal Bureau, Winding Gulf Operators Association, and Operators Association of the Williamson Field. Especial acknowledgment for detailed monthly production reports is made to: Thomas Allen, Colorado inspector of coal mines; James McSherry, director, Illinois Department of Mines and Minerals; the late M. J. Hartneady and his successor, J. I. Thomas, secretary, Pennsylvania Department of Mines; N. P. Rhinehart, chief, West Virginia Department of Mines; J. E. Bergin, chief inspector, Washington Department of Mines.

In the estimates for 1938 allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year. Production of mines on the border between two States has been credited to the State from which the coal is extracted rather than that in which the tipple is situated. If the coal is mined from lands in both States the tonnage has been apportioned accordingly.

The data in this report on the output of bituminous coal in 1936 and earlier years are based on detailed annual reports of production and mine operation courteously furnished by the producers. These reports depended on the voluntary cooperation of the producing companies. The system of voluntary reporting has been in use since 1883, when these statistics were inaugurated by the Geological Survey,

Digitized by Google

and has served a useful purpose in the measurement of production, supply and demand, trends of employment, mechanical equipment, operating practices, and output per man.

A combination of circumstances made it advisable for the National Bituminous Coal Commission to modify the method of compilation for 1937. On April 13, 1938, the Commission issued its Order 239, requiring all producers of bituminous coal to return a detailed accounting of the distribution of the entire production of each mine in 1937. Mines with rail or river connections were instructed to report their distribution on Commission form D–1. The form called for a statement of the tons of each individual size of coal shipped to each destination town. Mines selling only by truck reported on a simplified form known as D–2, which was adapted to their operations. This analysis of distribution was an essential prerequisite to the establishment of minimum prices under the coal act and was recognized as perhaps the most extensive task of fact-finding undertaken in the history of the bituminous-coal industry. The producers responded generously to the Commission's order, and the record of distribution developed from rail-connected mines to each ultimate destination is substantially complete.

Because of the size of the task and the great detail covered by the distribution analysis it was deemed inadvisable to require producers to prepare a separate report on production and mine operation. The items of tonnage produced had been covered on the distribution questionnaires in exceptional detail and had been rendered in each instance under affidavit of the producing company. It was therefore decided to utilize the tonnage statistics on forms D–1 and D–2 as the record of production for the year and to compile a record of employment, working time, and mechanical equipment by drawing upon the reports furnished by mine operators to the State inspection services. Nearly all of the coal-mining States require annual statistics to be filed with the local department of mines. In the few States that maintain no statistical record, other sources of information have been available. These reports, made available to the Commission in all necessary detail, have been used to assemble statistics on men employed, days operated, and tonnages produced by strip and underground mining for each coal-mining county in a form reasonably comparable with the Federal enumeration of previous years.

The aggregates and averages of men employed and working time derived in this way may differ from the corresponding figures published in the State reports for two reasons. First, the primary basis of the compilation is the tonnage record of each mine reported to the Coal Commission, against which has been matched the employment and operating record reported to the State. Although the two sources have been carefully checked for discrepancies there are differences in assignment of individual mines to districts and in the minimum size limit covered by the State and Federal enumerations that introduce discrepancies in the resulting totals. Second, the State data have in each instance been handled in a uniform manner, each step in the process of tabulating, editing, and summarizing the primary materials being taken with a view to rendering the final product as comparable as possible with the Federal series for the earlier years. Inasmuch as widely differing methods of analysis are used by the several States the uniform method followed by the authors may yield differing results.

Digitized by Google

Despite the effort at uniformity of treatment the statistician will realize that differences in the primary questionnaires used by the various States may impair the strict comparability of the employment record. The principal points of difference are discussed in the section dealing with labor statistics. Beginning with 1938 the Commission will resume collection of material for a direct report on employment, operating time, production, and mechanical equipment of the mines.

In the present chapter attention is centered on the detailed breakdown of tonnage produced according to method of shipment, which the distribution survey has made possible. For the first time figures are now available showing for each producing county the tonnage shipped to tidewater and the Great Lakes, the river movement, and the all-rail movement, the latter segregated between railroad fuel and commercial business. (See tables 6 and 39.)

Acknowledgment is made to the many individuals and agencies both public and private who have cooperated generously in making the survey possible.

## FINAL BITUMINOUS STATISTICS FOR 1936 AND 1937

Tables 6 to 13, 16, 18, 24, 25, and 32–42 give the final detailed statistics of bituminous mine operations in 1937. The subjects covered include production, number and size of mines, employment, equipment and methods of preparation, fuel economy, stocks, foreign trade, and world production. Statistics for 1938, where available, have been included in these tables.

Tables 14, 15, 17, 19–23, and 26–31 relate to 1936 and show data on mechanical loading, mechanical cleaning, stripping operations, and power drilling that were not included in the detailed report for 1936 owing to space limitations.

In accordance with the practice followed by the Bureau of Mines in previous years the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include the many small mines producing less than 1,000 tons per year that sell their output by wagon or truck.

[1] Includes coal reported as "shipped to distributors, destinations unknown," a small part of which may have been forwarded to tidewater or Great Lakes.
[2] Includes coal taken by locomotives at tipple.
[3] Includes coal made into beehive coke at mines in the following States in 1937: Colorado, 115,278; Pennsylvania, 3,787,102; Tennessee, 26,560; Utah, 12,271; Virginia, 412,192; West Virginia, 530,651 (including a small amount of coal made into briquets); a grand total of 4,884,054 tons in 1937, against 2,728,577 in 1936. Does not include coal shipped in by rail or truck from mines to beehive ovens for coking, such tonnage being included under rail or truck deliveries.
[4] The total production differs from the sum of the items shown by the amount of the changes in inventory and of tonnage not accounted for in the distribution analysis.
[5] Includes figures on lignite from Bureau of Mines; see Lignite Tables, 1937. "Loaded at mines for shipment," as published by Bureau of Mines, included under "all-rail"; "commercial sales by truck or wagon" and "other sales to local trade, etc.," as published by Bureau of Mines, included under "truck deliveries including local sales."

## PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the statistics of weekly and monthly production of bituminous coal first published in the Commission's Weekly Coal Reports. The figures are estimates based on daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. The estimates are revised afterward to agree with the results of the annual statistical reports from the coal producers; therefore, the figures given here differ slightly from those issued originally in the weekly reports.

For the method used in counting holidays see chapter on Coal in Mineral Resources of the United States, 1930, page 631.

TABLE 8.—*Estimated weekly production of bituminous coal in 1937*

| Week ended | Production (net tons) | Number of working days | Average production per working day (net tons) | Week ended | Production (net tons) | Number of working days | Average production per working day (net tons) |

TABLE 9.—*Monthly production of coal in 1937, by States, in thousands of net tons*

[The totals for the year are based on final complete returns to the National Bituminous Coal Commission from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based upon the best information available, in some States upon direct tonnage reports by operators to the State mine department, in most cases upon current records of railroad carloadings and waterway shipments.]

## NUMBER AND SIZE OF MINES

The 1937 survey of the bituminous-coal industry is based on records of 6,548 mines that produced 1,000 tons or more during the year. Although this is somewhat less than the 6,875 mines in the 1936 survey it is more than in any other year since 1927. The upward trend in the number of mines from the low of 5,427 in 1932 has been due in considerable measure to the opening of small truck mines in sections that have gained access to markets through the development of hard roads and cheap motor transport. The increase has been influenced by the presence of unemployed miners seeking a means of livelihood within their own trade. Furthermore, part of the rise in the number of mines resulted from the more intensive enumeration of small producers by both State and Federal agencies in recent years. This applies especially to 1936, when data on the production of numerous small mines were drawn from the code acceptance records.

The regulatory functions of the National Bituminous Coal Commission made it necessary to prepare a list of all coal producers, regardless of size, down to the smallest wagon mine or country bank. The list compiled originally has been revised from time to time in accordance with the latest information from the field. A total of 11,612 code acceptances was on file June 10, 1939, with the names of 4,303 supposed producers who had not applied for code membership. Many of the latter undoubtedly represent coal banks no longer in operation or are carried in the list of code members under another name. Although a majority of the nominal total of 15,915 producers have an output of less than 1,000 tons a year the record discloses a number of mines above the 1,000-ton limit that have not been listed previously by either Federal or State mine departments. Since the code acceptances included reports of the code members' output in 1936 they served as a supplementary record of production for that year. Some of the small mines that were added to the 1936 production on the basis of these records, however, did not furnish any data for 1937, so that the count for the latter year is slightly less complete.

The Federal enumerations for 1936 and 1937 were supplemented by increasing attention to statistics of small mines by certain State mine departments, such as those of Alabama, Indiana, Pennsylvania, and West Virginia.

The change in coverage of small mines, however, affects the comparability of the record only as far as the number of mines is concerned. Although nearly 60 percent of all mines included in the 1937 report fell in the less than 10,000 tons per year class the combined production for this group was less than 3 percent of the total for the country; consequently the change in the number of mines has very little effect upon comparability of the tonnage figures.

### TREND OF AVERAGE VALUE PER TON, F. O. B. MINES, 1929 TO 1937

Before the Bituminous Coal Act of 1937 was passed the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in the Bureau of Mines reports as representing "bituminous coal," and it covered all coal other than Pennsylvania anthracite produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, though continuing to compile data regarding lignite. Effective on the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission relate to all coal other than Pennsylvania anthracite and lignite, no exemptions other than lignite having been approved under the act.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though for convenience of the student, the combined average for the two is continued in a form as nearly comparable as possible to the old series.

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. The reporting operator was asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

It is also possible that the two sets of data are not precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series the reporting operator was instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to $1.761 per ton for bituminous coal excluding lignite. The average gross realization, as collected by the Coal Commission, was $1.831 per ton. The difference amounts to $0.07 per ton, an amount some-

Digitized by Google

what less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath they are to be accepted. The returns of earlier years, on a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by the operator down to 1936.

TABLE 11.—*Trend of average value per ton, f. o. b. mines, 1929–37*

| Year | Bituminous [1] coal (subject to regulation under 1937 Act) | Lignite [2] | Total |
|---|---|---|---|
| Average value per ton less selling expense (Bureau of Mines series): | | | |
| 1929 | $1.782 | $1.548 | $1.781 |
| 1930 | 1.702 | 1.556 | 1.701 |
| 1931 | 1.542 | 1.410 | 1.541 |
| 1932 | 1.313 | 1.313 | 1.313 |
| 1933 | 1.337 | 1.188 | 1.336 |
| 1934 | 1.751 | 1.387 | 1.749 |
| 1935 | 1.772 | 1.120 | 1.767 |
| 1936 | 1.761 | 1.061 | 1.756 |
| Average gross realization including selling expense (Coal Commission series): | | | |
| 1936 | 1.831 | [3] 1.061 | 1.826 |
| 1937 | 1.946 | [3] 1.080 | 1.939 |

[1] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.
[2] North Dakota, South Dakota, and the lignite counties of Montana and Texas.
[3] Figures of the Bureau of Mines, excluding selling expense as before. Data on sales realization were not collected from lignite mines by the Coal Commission.

## SPOT PRICES

Spot prices afford a basis for measuring the relative strength of the forces of demand and supply in the competitive market for bituminous coal. The market quotations published in the leading trade magazines usually are based on posted prices of larger producers, and oftentimes represent "asked" rather than "actual" prices.

Spot prices are not to be confused with sales realization, since the latter includes a large volume of coal either sold at relatively stable prices under long-term contracts or consumed by producers and their affiliates at purely nominal prices.

The following table of average spot prices is offered as an indication of trends in 1937 and 1938.

[1] Except as noted, these averages are based upon the following number of quotations: Prepared sizes: Chicago market, 25 quotations; Cleveland market, 29 quotations; Norfolk market, 18 quotations; Pittsburgh market, 3 quotations; total, 75 quotations. Run-of-mine: Chicago market, 7 quotations; Cleveland market, 2 quotations; Norfolk market, 7 quotations; Pittsburgh market, 0; total, 16 quotations. Screenings or slack: Chicago market, 19 quotations; Cleveland market, 11 quotations; Norfolk market, 7 quotations; Pittsburgh market, 2 quotations; total, 39 quotations. Total of all quotations used, 130.

[2] The increase in miners' wages after April 1, 1937, and the higher level of minimum prices during January and February 1938 must be taken into consideration when comparing prices for the first 3 months of 1937 and 1938.

[3] No quotations for Cleveland or Pittsburgh in January and February, or for Pittsburgh in June and December.

## LABOR STATISTICS

### MEN EMPLOYED

An average of 491,864 men was employed at bituminous-coal mines in 1937, an increase of 3 percent over the reported total of 477,204 for 1936. (See fig. 6.)

In general, these figures of average numbers employed represent the normal working force on the rolls of the mine during periods of active operation. The factor of intermittent employment, so characteristic of coal mining, has a marked effect on the earnings of the men, but it can best be treated by maintaining a separate record of the number of days operated during the year.

As outlined in the section "Sources of Data and Acknowledgments." the National Bituminous Coal Commission did not make a direct canvass of employment in the coal industry in 1937. All employment data in this report have been abstracted from records compiled by the various State departments of mines and other sources. Although the schedules that these agencies used in collecting the original data differed in many respects and although none were identical with the standard form used by the Bureau of Mines for the 1935 and by the Commission for the 1936 surveys the results for 1937 in general are fairly comparable with similar data in previous reports.

Digitized by Google

Among the problems encountered was classification of beehive-coke workers and office force. The standard schedule previously used by the Bureau of Mines had directed that these occupations be excluded. The State schedules for 1937 treated them in various ways. Some States followed the Federal practice and directed that coke and office workers be excluded. Others directed that they be reported. Where such was the practice an effort was made to deduct them from the total working force of the mine in question, and this could be done for Ohio and West Virginia, the figures for West Virginia excluding also supervisory officials. In Pennsylvania coke workers were deducted but office employees could not be. In Illinois, also, office employees were not eliminated. Several of the States, however, gave no specific instructions as to the occupations to be returned. It appears therefore that the employment figures in the present report may have a slight upward bias, due to the inclusion in some States of workers not

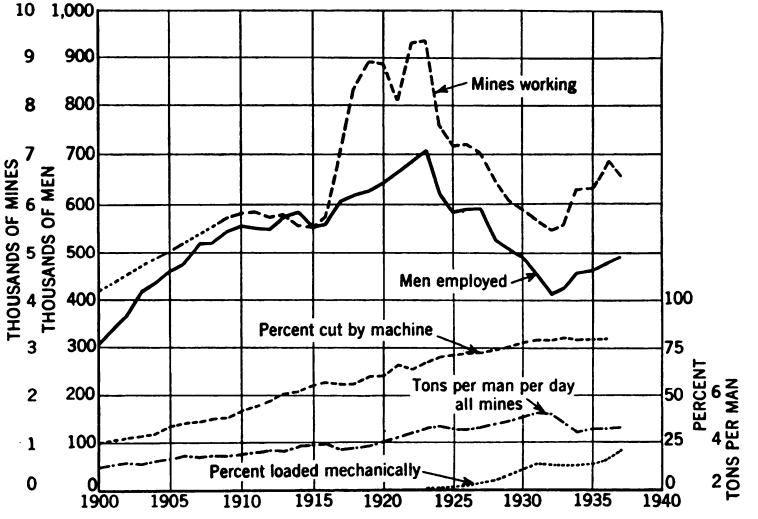

FIGURE 6.—Trends of employment, mechanization, and output per man at bituminous-coal mines, 1900–1937.

actually engaged in mining. The number so included is unimportant. The manufacture of beehive coke has shrunk to small proportions and outside of Pennsylvania and West Virginia, where coke workers are excluded, is confined to a few mines only. The number of office workers is small. In Ohio, for example, they comprised 0.9 percent of all employees. In West Virginia, where an occupational break-down is available, coke workers, office, and supervisory employees combined amounted to only 2.5 percent of all coal-mine employees.

The questionnaire for 1936 called for the number of men employed at each of the 12 pay periods nearest the fifteenth of the month. The average number of employees could then be computed accurately, excluding any pay periods when the mines were shut down and were giving employment only to maintenance men. Since employment data by months were procured by only a few of the States the former method of obtaining annual averages could not be used in the 1937

Digitized by Google

report. As a consequence of these as well as other differences comparisons between the employment data for 1937 and similar data for earlier years must be made with qualifications.[3]

In recent years a special problem has arisen in recording of employment through the adoption of local "share-the-work" agreements, by which the employees of a mine are divided into two crews or groups who work on alternate days. Such agreements for "staggering" or alternating the work are not to be confused with the practice of operating both a day and a night shift but relate rather to division of the available work between two groups of workers on the same shift, usually the day shift.

Specific inquiries regarding such agreements by the Department of Mines and Minerals in Illinois in 1937 indicated that 53 mines were operating with alternate crews under share-the-work agreements. If the number of men on the pay rolls had been used as a measure of employment instead of the average number of men working the employment figures for Illinois would have been increased approximately 7 percent. A small number of employees was involved in similar reports from Indiana.

The figures on "number of men employed" as given in this report are therefore somewhat less than the total number of men on the rolls in the States where there were mines that followed the practice of spreading employment by means of share-the-work agreements. No formal agreements for dividing work have been reported to the authors from mines outside of Illinois and Indiana in 1937; however, local share-the-work agreements may have existed in other fields, which were not reported, and occasionally at still other mines a certain amount of work-sharing may have been practiced without written agreement between operators and their employees.

### DAYS OPERATED

The average number of days of operation for bituminous-coal mines in 1937 was 193.[4] This represents a slight decline from the average of 199 days for 1936. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine without regard to size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of the typical mine employee.

### MAN-DAYS OF LABOR

Only a small proportion of the bituminous-mine operations, however, keep an accurate record of the man-days or man-hours worked. Consequently, man-days have been computed by multiplying the

[3] The statistical problems of measuring employment are fully discussed in two studies published by the Works Progress Administration, National Research Project on Reemployment Opportunities and Recent Changes in Industrial Techniques: Employment and Related Statistics of Mines and Quarries, 1935, Part I, Bituminous Coal, by F. G. Tryon and others, pp. 12–17; Mechanization, Employment, and Output Per Man in Bituminous-Coal Mining, by Willard E. Hotchkiss and others.

[4] Derived from the reports submitted by individual mines to the State inspection departments or other sources drawn upon. It is believed that a uniform return upon the standard questionnaire used by the Bureau of Mines in earlier years would show a slightly higher result, probably, 194 days. For practical purposes, however, the 1937 figures are comparable.

Digitized by Google

number of workers employed by the number of operating days. Although these computations were made for each individual mine the combined total is necessarily an approximation.

Until the American coal industry arranges to keep an accurate record of the man-days or man-hours of employment, all computations of accident rates, daily earnings, and output per man will remain subject to qualification. Meanwhile, the method of multiplying men by days must be accepted as the best available procedure.

Data for 1937 indicate that bituminous-coal-mine employees performed 95,015,641 man-days of labor during the year. Table 6 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines by States in 1937. Details by counties for 1937 are shown in table 39. Comparisons between 1937 and earlier years, however, are subject to the limitations imposed by the diversity of the schedules that the various agencies used in collecting the original data.

### LENGTH OF WORKING DAY

Data for computing the number of hours in the average working day of bituminous-coal miners were not available for 1937. Since there was no change in the provision of the union wage agreement regarding hours of work it can be assumed that the 7.02-hour-per-day average for 1935 and 1936 also would apply to 1937. For further discussion of length of working day and detailed statistics of earlier years, see Minerals Yearbook, 1937, pages 821–823.

## EQUIPMENT AND METHODS OF MINING AND PREPARATION, 1936–38

Statistics of strip mining, machine cutting, mechanical loading, and mechanical cleaning for 1936 were omitted from Minerals Yearbook, 1938, because of lack of space. To maintain the continuity of the series and to provide a permanent record of the essential data it seems advisable, therefore, to include the 1936 tables on equipment, methods of mining, and preparation in the following section along with such data for 1937 and 1938 as are now available.

## STRIPPING OPERATIONS IN 1936 AND 1937

### TABLE 14.—*Stripping operations of all types in bituminous-coal fields in 1936, by States and counties*

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these same mines are also shown]

| State and county | Number of strip pits | Number of power shovels | | | Coal produced (net tons) | | Number of employees | | | | Average number of days mines operated | Percent of county or State total mined by stripping | Man-days of labor | Average tons per man per day |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

| Grand total | 381 | 188 | 151 | 223 | 28,125,857 | 12,550 | 185 | 12.60 |

[1] Exclusive of coal produced by underground mining in the same operation.
[2] Items in these columns include underground mining conducted in the same operation.
[3] Includes one mine in North Dakota which has both underground and strip mining in the same operation.
[4] Arkansas, Colorado, Kentucky, and Wyoming.
[5] Includes operations in Alabama, Kentucky, Ohio, Pennsylvania, and Wyoming, in which the output was obtained by both methods. In addition to the 483,718 tons produced by stripping this group of 14 mines obtained 1,094,559 tons by underground methods, its total production by both methods being 1,578,277 tons.

TABLE 16.—*Stripping operations of all types in bituminous-coal fields in 1937, by States and counties*

| State and county | Number of strip pits | Coal produced (net tons) | | Number of men employed [1] | Average number of days mines operated [1] | Average tons per man per day [1] |
|---|---|---|---|---|---|---|
| | | Mined by stripping | Total at same mines [1] | | | |

## UNDERCUTTING MACHINES IN 1936

TABLE 17.—*Number of coal-cutting machines in bituminous-coal mines, average output per machine, and percentage of total product of underground mines cut by machines in 1936, by States* [1]

| State | Number of coal-cutting machines in use | | | Average output per machine (net tons) | Percent of total product of underground mines cut by machines |
|---|---|---|---|---|---|
| | "Permissible" | All others [2] | Total | | |
| Alabama | 69 | 276 | 345 | 25,688 | 72.8 |
| Arkansas | 54 | 95 | 149 | 8,538 | 81.2 |
| Colorado | 105 | 286 | 391 | 11,914 | 68.6 |
| Illinois | 345 | 940 | 1,285 | 28,760 | 88.4 |
| Indiana | 92 | 223 | 315 | 29,071 | 90.3 |
| Iowa | 64 | 49 | 113 | 11,649 | 35.7 |
| Kansas | 17 | 10 | 27 | 9,628 | 28.3 |
| Kentucky | 382 | 1,034 | 1,416 | 31,420 | 93.7 |
| Maryland | 16 | 22 | 38 | 15,960 | 35.6 |
| Michigan | 9 | 46 | 55 | 11,192 | 98.3 |
| Missouri | 48 | 44 | 92 | 9,703 | 58.6 |
| Montana and Texas | 17 | 39 | 56 | 29,181 | 64.9 |
| New Mexico | 29 | 16 | 45 | 9,172 | 25.8 |
| North Dakota | 20 | 5 | 25 | 23,070 | 68.0 |
| Ohio | 297 | 655 | 952 | 21,512 | 94.6 |
| Oklahoma | 64 | 46 | 110 | 8,530 | 78.4 |
| Pennsylvania | 2,247 | 1,125 | 3,372 | 24,868 | 76.9 |
| Tennessee | 27 | 85 | 112 | 31,940 | 70.0 |
| Utah | 53 | 67 | 120 | 23,635 | 87.4 |
| Virginia | 59 | 194 | 253 | 41,564 | 90.2 |
| Washington | 30 | 6 | 36 | 18,074 | 35.9 |
| West Virginia | 991 | 1,412 | 2,403 | 45,127 | 92.0 |
| Wyoming | 45 | 217 | 262 | 20,322 | 94.5 |
| Other States | | 2 | 2 | 1,583 | 20.6 |
| Total United States | 5,080 | 6,894 | 11,974 | 29,091 | 84.8 |

[1] Similar data for 1937 are not available.
[2] Probably includes some "permissible" machines not so specified by the operators.

## LOADING MACHINES AND CONVEYORS IN 1936, AND SALES IN 1937 AND 1938

*Mechanical loading in 1936 and 1937.*—The data for mechanical loading refer to all devices designed to reduce the labor of hand shoveling into mine cars. Data for 1936 are based on complete returns courteously furnished by coal operators. Figures for 1937 are preliminary and are based on various sources, as indicated in the footnotes to table 18.

TABLE 18.—*Bituminous coal mechanically loaded, 1935–37, by States, in net tons*

| State | 1935 [1] | 1936 | 1937 (preliminary) |
|---|---|---|---|
| Alabama | 1,303,653 | 1,741,452 | [2] 2,100,000 |
| Arkansas | 292,064 | 522,411 | [3] 550,000 |
| Colorado | 197,319 | 557,548 | [3] 1,018,039 |
| Illinois | 20,513,082 | 26,110,068 | [4] 28,344,362 |
| Indiana | 5,767,696 | 7,146,090 | [5] 7,426,306 |
| Iowa | | ([6]) | ([6]) |
| Kentucky | 533,250 | 658,747 | [2] 1,300,000 |
| Maryland | ([6]) | ([6]) | ([6]) |
| Missouri | ([6]) | | |
| Montana | 1,291,373 | 1,464,121 | [2] 1,431,000 |
| New Mexico | ([6]) | ([6]) | ([6]) |
| North Dakota | ([6]) | ([6]) | ([6]) |
| Ohio | 1,488,303 | 2,049,075 | [7] 3,204,102 |
| Oklahoma | ([6]) | ([6]) | ([6]) |
| Pennsylvania | 6,469,485 | 9,033,855 | [8] 11,951,639 |
| Tennessee | 233,579 | 290,220 | [2] 450,000 |
| Utah | 898,118 | 1,358,543 | [2] 1,835,000 |
| Virginia | 651,807 | 779,232 | [2] 1,500,000 |
| Washington | 429,617 | 608,488 | [9] 838,000 |
| West Virginia | 2,059,322 | 8,712,935 | [10] 15,490,863 |
| Wyoming | 4,530,032 | 5,189,263 | [11] 5,300,000 |
| Undistributed | 518,524 | 754,824 | 760,689 |
| Total United States | 47,177,224 | 66,976,872 | 83,500,000 |

[1] Bureau of Mines Minerals Yearbook, 1937, pp. 832, 887.
[2] Estimated on the basis of sales of new equipment in 1937.
[3] Thomas Allen, State inspector of coal mines, Colorado.
[4] James McSherry, director, Department of Mines and Minerals, Illinois.
[5] Jonas Waffle, managing director, Coal Trade Association of Indiana.
[6] Included in "Undistributed." Data for 1937 are based largely on telegraphic reports from operators.
[7] Milan W. Hranilovich, Division of Labor Statistics, Department of Industrial Relations, Ohio.
[8] M. J. Hartneady, Secretary of Mines, Pennsylvania.
[9] Telegraphic reports from mine operators.
[10] N. P. Rhinehart, chief, Department of Mines, West Virginia.
[11] Hugh McLeod, State mine inspector, Wyoming.

TABLE 19.—*Bituminous coal mechanically loaded underground in 1936, by types of machines*

| | Net tons | Percent |
|---|---|---|
| Loaded by machine: | | |
| Mobile loading machines | 40,969,625 | 90.1 |
| Scraper loaders | 1,272,466 | 2.8 |
| Conveyors equipped with duckbills and other self-loading devices | 3,240,411 | 7.1 |
| Total loaded by machine | 45,482,502 | 100.0 |
| Handled by conveyors: | | |
| Conveyors equipped with duckbills and other self-loading devices | 3,240,411 | 13.1 |
| Pit-car loaders | 10,538,331 | 42.6 |
| Hand-loaded conveyors | 10,956,039 | 44.3 |
| Total handled by conveyors | 24,734,781 | 100.0 |
| Recapitulation, less duplications: | | |
| Mobile loading machines | 40,969,625 | 61.2 |
| Scraper loaders | 1,272,466 | 1.9 |
| Conveyors equipped with duckbills and other self-loading devices | 3,240,411 | 4.8 |
| Pit-car loaders | 10,538,331 | 15.7 |
| Hand-loaded conveyors | 10,956,039 | 16.4 |
| Grand total loaded mechanically | 66,976,872 | 100.0 |

## TABLE 22.—*Mechanical loading underground in bituminous-coal mines in 1936, by States*

[The table includes all soft-coal mines that produced any part of their tonnage with the aid of mechanical loading devices in 1936. The mines have been grouped into three classes. The first includes those mines in which all of the tonnage mechanically loaded was obtained with machines that substantially eliminate hand shoveling; that is, mobile loaders, scrapers, and duckbill-equipped conveyors. It should be noted, however, that some of these mines make use of conveyors in conjunction with mobile loaders to perform the initial phase of transportation. The second class includes those mines in which all the tonnage mechanically loaded was obtained with hand-loaded conveyors or pit-car loaders. The third class includes mines that load with both types of machines]

| State | Number of mines | | | | Number of machines | | | | | Production mechanically loaded (net tons) | | | Total production of mechanized mines (net tons) | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Using loading machines only [1] | Using conveyors only [2] | Using both loading machines and conveyors | Total | Mobile loading machines | Scrapers | Conveyors equipped with duckbills and other self-loading devices | Pit-car loaders | Installations of hand-loaded conveyors [3] | Loaded by machines [1] | Handled by conveyors [2] | Total | Mines using loading machines only [1] | Mines using conveyors only [2] | Mines using both loading machines and conveyors | Total |

*Sales of mechanical loading equipment in 1937 and 1938.*—The trend of mechanization since 1936 is indicated by manufacturers' sales of equipment. Figure 7 shows the relative amount of coal mechanically loaded in 1936 in each producing State, together with the approximate capacity of new equipment installed in 1937 and 1938. The chart therefore affords a rough measure of the mechanical loading capacity available at the beginning of 1939, by States. Tables 24 and 25 give the details of sales.

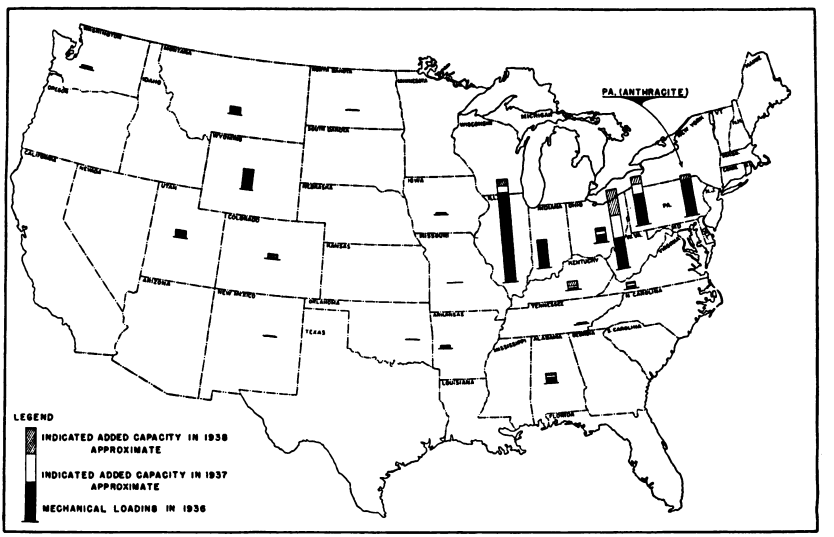

FIGURE 7.—Bituminous coal mechanically loaded in 1936 and approximate capacity of new equipment shipped in 1937 and 1938.

TABLE 24.—*Sales of mechanized loading equipment in 1937 and 1938 compared with total number of machines in active use in preceding years*

| | Number of machines in active use, as reported by mine operators | | | | | | | | Number of machines sold as reported by 29 manufacturers | |
|---|---|---|---|---|---|---|---|---|---|---|
| | 1929 | 1930 | 1931 | 1932 | 1933 | 1934 | 1935 | 1936 | 1937 | 1938 |

[1] Includes hand-loaded conveyors and conveyors equipped with duckbills or other self-loading heads. The figures of number in use in 1936 are not exactly comparable with the number sold in 1937 and 1938 because of uncertainties in defining what constitutes a conveyor. The comparison, however, will serve to indicate which regions have made the largest proportionate increases.
[2] Mostly in Kentucky.
[3] Mostly in Illinois.
[4] Colorado, Montana, New Mexico, North Dakota, Utah, and Wyoming.
[5] Arkansas, Montana, Utah, and Wyoming.
[6] Colorado, Montana, Oklahoma, Utah, and Wyoming.
[7] Arkansas, New Mexico, Oklahoma, and Wyoming.
[8] Wyoming.
[9] Arkansas, Colorado, Iowa, Montana, Utah, Washington, and Wyoming.
[10] Arkansas, Colorado, Iowa, Utah, and Wyoming.
[11] Arkansas, Colorado, Iowa, Oklahoma, Utah, and Wyoming.

## POWER DRILLING IN UNDERGROUND MINES IN 1936

In 1936, a total of 111,950,000 tons (27.2 percent) of the deep-mined bituminous-coal output was produced from working places in which the shot holes were drilled by mechanical power drills as contrasted with hand drills. Power drills are in use or on trial in nearly every important coal-producing county. In some counties the production by power drills is substantial; in others it is insignificant. The conditions under which this kind of labor-saving device is used differ widely, not only geographically but also as to thickness of beds, pitch of seams, and hardness of the coal itself. The widespread acceptance of this mechanical tool under varying conditions indicates an extensive market for drilling machinery, since three-fourths of the Nation's production of bituminous coal is still hand-drilled. The application of power drills is another step toward substitution of mechanical devices for hand labor.

The amount of bituminous coal produced by the use of electric drills amounted to 100,050,000 tons and by compressed-air drills 11,900,000, a total of 111,950,000 tons. More than 88 percent of the total produced by compressed-air drills came from Western Pennsylvania.

For details by States showing tons produced by the two types of drills, percentage power-drilled compared with machine cutting and mechanical loading, and total production of mines using one or more

drills in coal or rock or both, see "A Reconnaissance of Power Drilling in Underground Bituminous-Coal Mines in 1936," by J. J. Gallagher and L. N. Plein in Mining Congress Journal, January 1939, pages 26–28; also National Bituminous Coal Commission Weekly Coal Report 1118, December 17, 1938.

## MECHANICAL CLEANING IN 1936

Data on mechanical cleaning of coal in 1936 are given in tables 26 to 31. Although figures for 1937 and 1938 are not available reports from manufacturers of mechanical cleaning equipment indicate that a large number of new installations were made in these years.

TABLE 26.—*Bituminous coal mechanically cleaned by wet and pneumatic methods, 1935–36, in net tons of clean coal*

| | 1935 | 1936 | Increase in 1936 | |
|---|---|---|---|---|
| | | | Net tons | Percent |
| By wet methods: | | | | |
| At the mines | 31,006,643 | 42,795,529 | +11,788,886 | +38.0 |
| At central washeries operated by consumers | 5,849,845 | 7,708,499 | +1,858,654 | +31.8 |
| Total wet | 36,856,488 | 50,504,028 | +13,647,540 | +37.0 |
| By pneumatic methods | 8,504,533 | 10,590,948 | +2,086,415 | +24.5 |
| Grand total | 45,361,021 | 61,094,976 | +15,733,955 | +34.7 |

TABLE 27.—*Bituminous coal cleaned, 1935–36, by classes of equipment in actual operation*

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania are included.]

| Type of equipment | Plants in operation | | Net tons of clean coal | | Increase in 1936 | | Percent cleaned by each type | |
|---|---|---|---|---|---|---|---|---|
| | 1935 | 1936 | 1935 | 1936 | Net tons | Percent | 1935 | 1936 |
| Wet methods: | | | | | | | | |
| Jigs | 138 | 154 | 15,735,039 | 23,417,266 | +7,682,227 | +48.8 | 34.7 | 38.3 |
| Concentrating tables [1] | 9 | 8 | 1,117,789 | 1,843,167 | +725,378 | +64.9 | 2.5 | 3.0 |
| Jigs in combination with concentrating tables [1] | 15 | 16 | 1,549.422 | 2,612,666 | +1,063,244 | +68.6 | 3.4 | 4.3 |
| Launders and upward-current classifiers | 93 | 98 | 18,454,238 | 22,630,929 | +4,176,691 | +22.6 | 40.7 | 37.1 |
| Total wet | 255 | 276 | 36,856,488 | 50,504,028 | +13,647,540 | +37.0 | 81.3 | 82.7 |
| Pneumatic methods | 65 | 66 | 8,504,533 | 10,590,948 | +2,086,415 | +24.5 | 18.7 | 17.3 |
| Grand total | [2] 320 | [2] 342 | 45,361,021 | 61,094,976 | +15,733,955 | +34.7 | 100.0 | 100.0 |

[1] A more representative figure for the use of wet tables is indicated by combining the totals for concentrating tables with the total for jigs in combination with concentrating tables. This shows a net gain of 1,788,622 tons (67.1 percent) for 1936.

[2] Plants using both wet and pneumatic types—32 in 1935; 31 in 1936.

*Relation between raw coal, clean coal, and refuse.*—For every 100 tons of raw coal that passed into the cleaning systems about 90.5 tons came out as clean, merchantable product, and about 9.5 tons went to the refuse bank as worthless. Figures as to the amount of refuse resulting from cleaning operations seldom have been published, for several reasons: many mine operators cannot furnish exact figures, and the nature of the seam, the methods of mining, and the specific gravity at which the separation is made affect the percentage of refuse. With these factors in mind table 31 is offered as an indicator of the percentage of refuse resulting from mechanical cleaning in the various States.

TABLE 31.—*Relation between total production, raw coal, and refuse resulting from cleaning operations in 1936, by States, in net tons*

| State | Total production of mines with cleaning plants | Result of cleaning operations | | | Percent of refuse to raw coal | Percent of clean coal to total mine production |
|---|---|---|---|---|---|---|
| | | Raw coal | Clean coal | Refuse | | |
| Alabama | 11,135,961 | 11,119,454 | 9,922,514 | 1,196,940 | 10.8 | 89.1 |
| Colorado | (1) | (1) | (1) | (1) | 8.5 | 26.6 |
| Illinois | 17,191,716 | 6,675,210 | 5,613,522 | 1,061,688 | 15.9 | 32.7 |
| Indiana | 4,848,150 | 2,556,083 | 2,198,067 | 358,016 | 14.0 | 45.3 |
| Kentucky | 2,495,819 | 564,875 | 514,647 | 50,228 | 8.9 | 20.6 |
| Missouri and Kansas | 2,349,664 | 2,053,539 | 1,771,870 | 281,669 | 13.7 | 75.4 |
| Ohio and Michigan | 2,880,574 | 1,536,329 | 1,331,545 | 204,784 | 13.3 | 46.2 |
| Pennsylvania | (1) | (1) | (1) | (1) | 6.9 | 53.0 |
| Tennessee | 551,737 | 305,947 | 257,987 | 47,960 | 15.7 | 46.8 |
| Virginia | 1,853,615 | 551,211 | 473,992 | 77,219 | 14.0 | 25.6 |
| Washington | 1,502,214 | 1,429,682 | 1,203,783 | 225,899 | 15.8 | 80.1 |
| West Virginia | 42,034,038 | 16,408,308 | 15,360,671 | 1,047,637 | 6.4 | 36.5 |
| Undistributed [2] | 28,558,729 | 15,832,849 | 14,737,879 | 1,094,970 | 5.5 | 22.0 |
| Total at mines only | 115,402,217 | 59,033,487 | 53,386,477 | 5,647,010 | 9.6 | 46.3 |
| Consumer plants | | 8,128,518 | 7,708,499 | 420,019 | 5.2 | |
| Grand total | | 67,162,005 | 61,094,976 | 6,067,029 | 9.0 | |

[1] Included in "Undistributed."
[2] Tonnage figures include Arkansas, Colorado, Maryland, Montana, New Mexico, and Pennsylvania. Percentage figures represent results for Arkansas, Maryland, Montana, and New Mexico only.

## SIZES PRODUCED

Complete statistics of the tonnage of each size of bituminous coal shipped in 1937 are given in the following publications of the Coal Commission, based on the distribution survey:

Key Table of Sizes and of Size Groups Proposed by District Boards in Western Districts; December 12, 1938.
Key Table of Sizes and of Size Groups Proposed by District Boards in Eastern Districts; January 4, 1939.
Key Table of Sizes and of Size Groups Proposed by District Boards in Middle Western Districts; January 4, 1939.

These tables give for the first time accurate data on the number and comparative importance of the manifold sizes in which bituminous coal is prepared for the market at present.

The analysis shows that in District 7 of the coal act no less than 117 different sizes were prepared and marketed in 1937. In some districts a still greater diversity of sizes was recorded.

Copies of these tables may be had on application to the United States Department of the Interior, Washington, D. C.

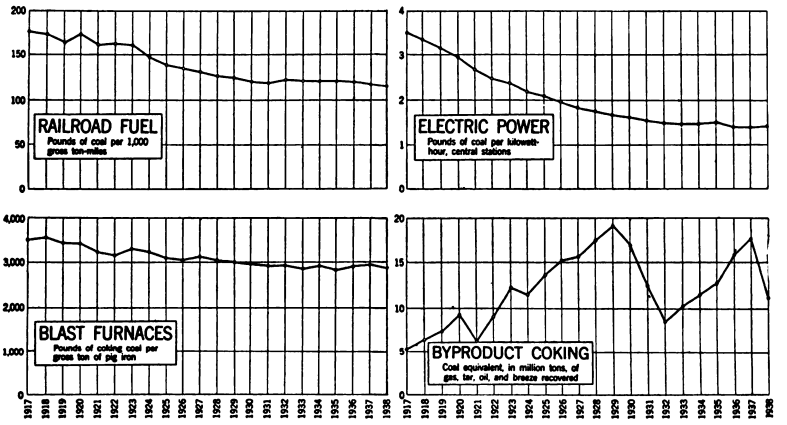
## FUEL EFFICIENCY

TABLE 32.—*Indicators of the effect of fuel economy on consumption of coal per unit of performance since the World War*

| | Pounds | Reduction from base period (percent) |
|---|---|---|
| Steam railroads: | | |
| Pounds per 1,000 gross ton-miles freight service: | | |
| Average, 1919–20 | 170 | |
| Average, 1937 | 117 | 31.2 |
| Average, 1938 | 115 | 32.4 |
| Pounds per passenger-train car-mile: | | |
| Average, 1919–20 | 18.5 | |
| Average, 1937 | 15.1 | 18.4 |
| Average, 1938 | 14.9 | 19.5 |
| Electric-public-utility power plants: | | |
| Pounds per kilowatt-hour, 1919 | 3.2 | |
| Pounds per kilowatt-hour, 1937 | 1.4 | 56.2 |
| Pounds per kilowatt-hour, 1938 | 1.4 | 56.2 |
| Iron and steel—pounds coking coal per ton of pig: [1] | | |
| 1918 | 3,577 | |
| 1937 | 2,917 | 18.5 |
| 1938 | 2,865 | 19.9 |
| Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–38, expressed as percent of coal used for all coke in 1938 [2] | | 18.2 |

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are treated in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and cooking, and to a small extent for automotive fuel.



RAILROAD FUEL
Pounds of coal per 1,000 gross ton-miles
ELECTRIC POWER
Pounds of coal per kilowatt-hour, central stations
BLAST FURNACES
Pounds of coking coal per gross ton of pig iron
BYPRODUCT COKING
Coal equivalent, in million tons, of gas, tar, oil, and breeze recovered

FIGURE 8.—Trends in fuel efficiency in the United States, 1917–38.

## DISTRIBUTION

Tables showing the movement of coal to the Great Lakes, tidewater, New England, and certain other major channels of distribution are included in the Monthly Coal Distribution Reports.

Details of distribution by sizes and grade from each origin district to each consuming market area are being published by the Divisions of Research and Statistics, National Bituminous Coal Commission.

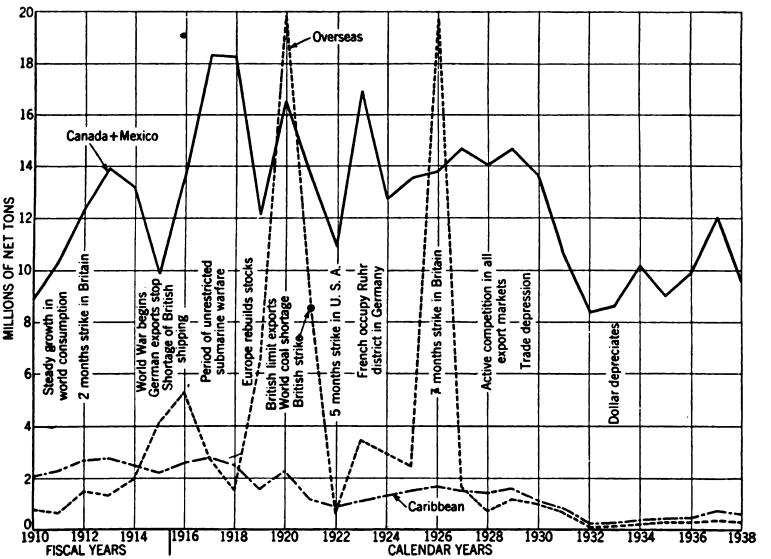

FIGURE 9.—Exports of bituminous coal to Canada and Mexico, the Caribbean, and "overseas" destinations, 1910–38.

*Shipments to Alaska, Hawaii, Puerto Rico, and the Virgin Islands.*—In addition to export trade proper the United States supplies a small tonnage of anthracite and bituminous coal to Alaska, Hawaii, Puerto Rico, and the Virgin Islands. Shipments of bituminous coal to each of these possessions in 1938 were as follows: Alaska, 23,465 net tons; Hawaii, 773; Puerto Rico, 19,967; and Virgin Islands, 93,065. Comparative shipments for 1937 were: Alaska, 24,562 net tons; Hawaii, 8,238; Puerto Rico, 20,465; and Virgin Islands, 68,359.

| Bituminous and anthracite (by subtraction) | 1,094,000 | 1,120,000 | 1,220,000 | 1,284,000 | 1,177,000 |

[1] Estimate included in total.
[2] Exclusive of mines in the Saar.
[3] Mines under French control until Mar. 1, 1935.
[4] Production of the most important coal-producing areas.
[5] Excludes coal (about 550,000 metric tons) consumed by the miners.

## DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 39 for each county in the United States in which three or more operators produced coal in 1937. If there were less than three producing companies the figures for two or more counties have been combined to avoid disclosing individual returns, unless permission to publish has been granted by the producers.

In this series the reported production is classified according to the principal channels of distribution or use. The distribution schedules (N. B. C. C. form D–1 and D–2), which constituted the primary source material for the 1937 statistics permitted a much more detailed analysis of the movement of coal from producing mines to consumer destinations than has ever been possible heretofore.

Digitized by Google

The classifications selected for this purpose did not coincide with the groupings that had been used in the annual series for 1936 and earlier years. For purposes of presentation in this report the 1937 figures have been grouped and rearranged in the order that most nearly corresponds to the old series. The resulting data are fairly comparable, therefore, with the statistics for years prior to 1937.

The following descriptions of the classification groups have been taken very largely from the instructions on the 1937 distribution schedules. They are given here to define more clearly the limits to the various groups.

*Shipments to tidewater.*—"All coal dumped over tidewater piers."

*Shipments to Great Lakes.*—"All coal dumped over piers on Lake Erie and Lake Ontario."

*River and ex-river.*—River coal represents all bituminous "Coal moving by river barges whether loaded directly at the mine or first transported from mine to river tipple by rail or truck." Ex-river includes "Coal unloaded from river barges which is shipped inland by rail or truck to points beyond the river port of unloading." Double counting between river and ex-river has been avoided.

*All-rail other than railroad fuel.*—"All shipments (except railroad fuel) which move from mine to ultimate destination by rail, including car-ferry across Great Lakes and to Cuba." Coal reported by producers as "Shipped to distributors, destinations unknown," has also been included for convenience in the all-rail classification, although a small part of it doubtless moved by lake or tide.

*Railroad fuel, all-rail.*—"All sales of coal to railroads delivered all-rail, including coal furnished to locomotive tenders at tipple." Note that coal taken by locomotives at tipple was formerly classified with "Other sales to local trade." This item, however, is comparatively small.

*Total loaded at mines for shipment by rail or water.*—Combines the five preceding items into a total reasonably comparable with the classification in previous reports entitled "Loaded at mines for shipment by rail or water."

*Truck deliveries including local sales.*—"All coal loaded at mines for delivery by truck or wagon, including local sales." Excludes coal "used by mine employees, mine fuel and coal made into beehive coke or briquets at mine." Neither this nor the following item, "Used by mine employees," is directly comparable with individual items in the old series. If these two items are combined, however, the resulting figure is fairly comparable with the combined total for the two classifications in the old series entitled "Commercial sales by truck or wagon" and "Other sales to local trade, or used by employees, or taken by locomotives at tipple." The discrepancy between the individual groups arises from the inclusion of "Other local sales" with truck deliveries in 1937 rather than with "Coal used by mine employees," as in earlier years. Coal consumed for manufacturing or other industrial uses at the mine is responsible for the more significant shifts between the two groups.

*Used by mine employees.*—See explanatory note for "Truck deliveries, including local sales," above.

*Mine fuel or made into beehive coke at mines.*—This item is directly comparable with the former classification "Used for power and heat or made into coke at mines."

The data used in this report, like those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. This fact should be borne in mind also when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise in large measure from variations in coverage of the State reports, some of which include data for all mines regardless of size and others only data for mines employing more than a specified minimum number, which ranges from 2 to 10 men. Certain State reports also include washery and picking-table refuse. In the statistics here given refuse is excluded.

TABLE 39.—*Production, men employed, days operated, and output per man per day at bituminous-coal mines in specified States and counties in 1937*

[Note that figures relate only to active mines of commercial size, excluding truck and wagon mines producing less than 1,000 tons. Waste and refuse are not included in tonnage. For source of data used in compiling 1937 figures and comparability with earlier years, see sections of this report on "Sources of Data and Acknowledgments" and "Detailed Statistics, by States and Counties."]

| Lincoln | | | | 178,608 | 317,583 | 496,191 | 44,463 | 4,196 | 11,179 | 558,362 | 601 | 209 | 4.44 |
| Sheridan | | | | 256,203 | 321,485 | 577,688 | 65,352 | 3,519 | 2,365 | 649,643 | 356 | 146 | 12.49 |
| Sweetwater | | | | 543,489 | 3,005,381 | 3,548,870 | 6,071 | 21,587 | 55,992 | 3,632,566 | 2,893 | 209 | 6.00 |
| Other counties (Big Horn, Natrona, and Uinta)[4] | | | | 3,491 | 4,691 | 8,182 | 10,927 | 166 | | 19,275 | 31 | 217 | 2.86 |
| Total Wyoming | | | | 1,325,730 | 4,204,500 | 5,530,230 | 222,544 | 36,290 | [4] 125,554 | 5,918,359 | 4,743 | 204 | [7] 6.11 |

[1] Includes coal reported as "shipped to distributors, destinations unknown," a small part of which may have been forwarded to tidewater or Great Lakes.
[2] Includes coal taken by locomotives at tipple.
[3] The total production differs from the sum of the items shown by the amount of the changes in inventory and of tonnage not accounted for in the distribution analysis.
[4] No coal was made into beehive coke at mines in 1937.
[5] Includes 115,278 tons made into beehive coke at mines in Las Animas County in 1937 (93,941 tons in 1936).
[6] "Other counties" include, Adams, Bond, Brown, Crawford, Hancock, Logan, Macon, Marion, Putnam, Scott, Warren, White, and Will.
[7] Much of the output of the State is obtained from strip pits or by the use of loading machines, in which types of operations the production per man per day is large.
[8] Production of Home Riverside and Alston mines is credited to Missouri rather than to Kansas.
[9] The output is chiefly obtained from strip pits, in which the production per man per day is large.
[10] Data on lignite compiled by L. Mann, Bureau of Mines; see Lignite Tables, 1937. "Loaded at mines for shipment," as published by Bureau of Mines, included under "all-rail"; "commercial sales by truck or wagon" and "other sales to local trade, etc.," as published by Bureau of Mines, included under "truck deliveries including local sales."
[11] Includes coal made into beehive coke at mines in the following counties in 1937: Bedford, 63,805; Blair, 2,732; Cambria, 67,083; Fayette, 2,753,684; Indiana, 302,980; Westmoreland, 596,818. The State total is 3,787,102 tons in 1937 against 1,907,101 tons in 1936. Does not include coal shipped in by rail or truck from mines to beehive ovens for coking, such tonnage being included under rail or truck deliveries.
[12] Includes 25,645 tons made into beehive coke at mines in Grundy County and 915 tons in Morgan County in 1937, compared with 6,886 tons in Grundy County in 1936.
[13] Includes 12,271 tons made into beehive coke at mines in Carbon County in 1937 (9,754 tons in 1936).
[14] Figures compiled by L. Mann, Bureau of Mines; see Anthracite and Semianthracite Outside of Pennsylvania Tables, 1937. "Loaded at mines for shipment," as published by Bureau of Mines, included under "all-rail"; "commercial sales by truck or wagon" and "other sales to local trade, etc.," as published by Bureau of Mines, included under "truck deliveries including local sales."
[15] Includes 412,192 tons made into beehive coke at mines in Wise County in 1937 (330,130 tons in 1936).
[16] Includes 530,651 tons made into beehive coke at mines in Fayette and Preston Counties, and briquets in McDowell County; figures for individual counties cannot be disclosed.

[3] Revised figures.

## STATISTICS OF LIGNITE AND HARD COAL OUTSIDE OF PENNSYLVANIA

In statistics of the Bureau of Mines the anthracite industry of Pennsylvania and the bituminous-coal industry are shown separately. Following general trade usage, the statistics of the bituminous-coal industry, as given in this and previous reports, include lignite and the small quantities of anthracite and semianthracite produced outside of Pennsylvania. Due, however, to the geographical location of the three principal lignite fields and to the inherent characteristics of hard coal, these coals have been deemed important enough to be treated in separate tables in previous issues of the Minerals Yearbook. To maintain the continuity of this supplementary series, the classification of producers heretofore used has been retained in tables 41 and 42 without reference to final determination of their status under section 17 (b) of the Bituminous Coal Act of 1937.

Preliminary estimates for 1938 indicate an output of 3,008,000 tons of lignite compared with 3,218,419 tons in 1937 and 3,109,689 in 1936. Summary statistics, by States, for 1937 are given in table 41.[6]

The production of hard coal outside of Pennsylvania during 1938 is estimated at 369,000 tons. Comparative tonnages for 1937 and 1936 were 468,852 and 520,452, respectively. Detailed data by States are presented in table 42.

[6] Tables 41 and 42 were compiled by L. Mann, Coal Economics Division, Bureau of Mines. Detailed statistics for these items were published in mimeographed form by the Bureau of Mines as follows: Lignite, January 17, 1939; anthracite and semianthracite outside of Pennsylvania, November 5, 1938. Copies of these tables are available for free distribution upon request.

# PENNSYLVANIA ANTHRACITE

By M. VAN SICLEN, L. MANN, and J. R. BRADLEY

## SUMMARY OUTLINE

| | Page |
|---|---|
| General summary | 831 |
| Salient statistics | 833 |
| Pennsylvania anthracite industry | 836 |
| Weather | 836 |
| Competitive fuels | 836 |
| Consumption | 838 |
| Nonfuel uses | 839 |
| Method of transport | 839 |
| Stocks | 840 |
| Promotional and regulatory activities | 841 |
| Technologic developments | 842 |
| Sources and acknowledgments | 842 |
| Production | 843 |
| By weeks and months | 843 |
| By regions, fields, and counties | 844 |
| Production—Continued. | |
| Fresh-mined and culm-bank coal, breaker, and washery product | 847 |
| Shipments, by regions and sizes | 848 |
| Prices and average sales realization | 852 |
| Number of operations | 854 |
| Labor statistics | 854 |
| Equipment and methods of mining | 856 |
| Mechanical loading | 856 |
| Cutting machines | 858 |
| Strip-pit mining | 858 |
| Dredge operations | 859 |
| Foreign trade | 859 |
| The Canadian market | 860 |

Pressure from competitive fuels and a year of abnormally high temperatures combined to lessen the demand for anthracite, and total production fell from 51,856,000 net tons in 1937 to 46,099,000 in 1938, or 11 percent, thus receding to a point below the depression years of 1932 and 1933. This compares with a drop of 23 percent in the production of bituminous coal. The corresponding figures for commercial shipments were 46,203,000 tons in 1937 and 41,064,000 in 1938. The figures are exclusive of the output of unauthorized mines, which was closely estimated by the Pennsylvania Department of Mines at 2,500,000 net tons in 1938. This activity is concentrated largely in the Southern and Western fields. The industrial recession in 1938 had little effect on consumption of anthracite, which is primarily a fuel for domestic heating.

Prices at the mine for both domestic and steam sizes were slightly higher in 1938 than in 1937, and wholesale prices for coal on tracks at destination were about the same. Shippers to the larger markets, especially New York, were afflicted by price cutting among the producing interests on so-called distress coal, despite attempts at stabilization. As indicated by operating reports, the average of mine costs was affected adversely by the smaller production and by sporadic suspensions of work unauthorized by the labor union. Taxes remained high, and freight rates increased slightly during the year.

Withdrawal of the Canadian import duty was not achieved when the trade agreement with Canada was made, but the Canadian excise tax was removed on April 26, 1939.

New and revised State laws covering occupational diseases and workmen's compensation went into effect on January 1, 1938, which, if accepted, would greatly increase mining-company costs. However, many of the companies rejected the revised compensation act as permitted under the law.

More encouraging were the widening effect of educational and testing work done by Anthracite Industries, Inc., and the representation of the industry by the Anthracite Institute at all public and trade matters of interest, as well as their prompt publication of trade statistics.

Provisions against the sale of illegally mined anthracite were enforced by adjoining States to the extent of funds available, and this trade became restricted more and more to Pennsylvania.

The faith of local chambers of commerce and of the people of the region generally in the future of their principal industry was shown by the raising of funds for a generous anthracite display at the New York World's Fair of 1939. The fundamental factors underlying the industry—the character of anthracite and its geographic location near thickly populated industrial centers requiring both heat and power—remain permanent and favorable.

No general legislation dealing with stabilization of the anthracite industry was passed during the year by either the State or the Federal Government.

Statistical trends in the industry for 1938 are shown in the following tables:

*Pennsylvania anthracite industry.*—Trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite also are mined in parts of Virginia, Arkansas, Colorado, and New Mexico. Locally these coals represent distinct and important industries, but the tonnages involved are small and for statistical convenience usually are grouped with the totals of the bituminous-coal industry. Tables 41 and 42 of the chapter on Bituminous Coal in this volume record the 1937 production of anthracite and semianthracite outside of Pennsylvania; data for 1938 are not yet available.

The Pennsylvania anthracite industry, as here defined, includes all nonbituminous fields of that State. Trade usage commonly includes with Pennsylvania anthracite the output of the Bernice Basin in Sullivan County, although the coal of this basin is officially classified as semianthracite.

*Weather.*—As anthracite is essentially a household fuel the weather has an important bearing on the demand. Mild weather in the spring of 1938 and again in the late fall adversely affected the anthracite market.

The year 1938 was much warmer and slightly wetter than normal. The New England States and New York are important anthracite markets. In the New England States monthly departures from normal temperatures were January −1.3°, February +3.4°, March +1.9°, April +2.6°, October +3.0°, November +2.6°, and December +2.1°. In New York temperature deviations from normal were January −0.9°, February +5.1°, March +4.9°, April +2.4°, October −0.4°, November +2.9°, and December −0.5°. Thus, in New England during the 7 coal-burning months only 1 month was below normal and in New York only 3 months.[1]

It is thus evident that the above-normal temperatures of the leading consuming centers were responsible for a marked drop in demand for anthracite.

*Competitive fuels.*—The principal markets for Pennsylvania anthracite are the New England States, New York, New Jersey, Delaware, Maryland, Pennsylvania, and the District of Columbia, which took 84.2 percent of the production of anthracite in 1936 and 80.2 percent in 1937. Of the mineral fuels available for use in these States (excluding the important item of bituminous coal, for which no data are available, and natural and liquefied gases), the share contributed by anthracite continued to decline, as did the total apparent consumption of all fuels. Consumption of anthracite, briquets, coke, and fuel oils (in terms of coal) was equivalent to 71,706,000 tons in 1936 and declined 3.4 percent to 69,293,000 tons in 1937. Comparable data for 1938 are not yet available. Of the total fuels in 1936 and 1937, respectively, Pennsylvania anthracite comprised 64.1 and 60 percent; imported anthracite, 0.9 and 0.6 percent; briquets, 0.2 and 0.1 percent; coke for domestic use, 7.0 and 5.8 percent; imported coke, 0.3 and 0.2 percent; and heating and range oils, 27.5 and 33.3 percent. In 1937 the coal equivalent of heating and range oils available for use was more than half the tonnage of anthracite. The losses in anthracite consumption were balanced by gains in the use of heating and range oils, which increased 17 percent over 1936. Details are shown in table 3.

[3] An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped to New York City.
[4] Bureau of Foreign and Domestic Commerce.
[5] Converted to coal equivalent on the basis of 4 barrels of fuel oil equaling 1 ton of coal.
[6] Estimated on the basis of distribution in 1936.

Sales of coke for domestic heating, fuel briquets and packaged fuel, manufactured gas for domestic use and for house heating, and natural gas for all purposes for the most part either declined or increased only moderately in 1938. Noteworthy exceptions were the increases of 19.5 percent in sales of manufactured gas for house heating in New Jersey and of 17 percent in New York. Sales of range oil and heating oils rose considerably in 1938, and sales of liquefied petroleum gases increased 42 percent over 1937. Detailed figures are shown in table 4.

The general slackening in 1938 was reflected not only in the consumption of fuels but also in the shipment of mechanical coal stokers, oil burners, and distillate oil burners. The sole exception was a 38-percent increase in factory sales of anthracite-burning types of stokers—from 9,074 units in 1937 to 12,561 in 1938.

In addition to the competition of other fuels, an invisible factor tending to decrease consumption is the more efficient combustion of anthracite, which, however, is probably less than that achieved in the technology of bituminous coal. Other factors tending to decrease consumption are the wider use of insulation in house construction, improved radiation systems, the relative increase in two-family and apartment dwellings, and the uniformly high grade of prepared sizes of anthracite which contain more heat units per ton.

[1] A considerable part of the Buckwheat No. 1 is used for domestic purposes.
[2] Production plus imports less exports where available.
[3] Subject to revision.
[4] Partly estimated.
[5] An estimated two-thirds is used for domestic purposes.
[6] Exact data not available; estimated between 55,000,000 and 77,000,000 tons a year, including lignite and anthracite and semianthracite outside of Pennsylvania which are shown separately.
[7] Range oil is a light distillate used for house heating, hot-water heating, and cooking.
[8] Data not available.
[9] Includes all grades of fuel oil used for heating buildings.
[10] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[11] American Gas Association. Data revised as of March 1939.

*Consumption.*—Calculated consumption of anthracite—production, plus imports, minus exports, and plus or minus changes in producers' stocks at the beginning and end of the year—was 45,200,000 net tons in 1938, a decrease of 10 percent compared with 1937. Sales of illicit coal have not been considered in either year.

Consumption of anthracite by railroads in 1938 ranged from a high of 154,411 tons in January to a low of 90,750 tons in June, and the total for the year was 5.5 percent less than in 1937. Consumption by electric-power utilities ranged from 127,528 to 198,955 tons a month and was 4.1 percent above 1937. Other industrial consumption

Digitized by Google

declined 10 percent. Total industrial consumption was about 135,000 tons less than in 1937.

According to a survey of the Commonwealth of Massachusetts, Division on the Necessaries of Life, the consumption of domestic sizes of anthracite in Massachusetts in the coal year 1937–38 (2,483,000 tons) was virtually the same as in 1936–37, and that of buckwheat (192,000 tons) increased 8 percent.

Imports of foreign anthracite into the New England States in 1938 (363,000 net tons) comprised 8 percent of the total receipts of anthracite into that region.

*Nonfuel uses.*—The Anthracite Institute reports that in 1938, according to replies received from companies producing 68 percent of the commercial output, more than 216,000 tons of anthracite, mostly Buckwheat No. 4 and smaller, were sold for nonfuel uses. The greatest nonfuel uses for anthracite were as follows: Reducing zinc, for which 123,000 tons were used; sintering iron ores, which required 45,000 tons; and carbonizing steel, for which 30,700 tons were used. The sale of anthrafilt continued to increase.

*Method of transport.*—There was a drastic decline in rail shipments of Pennsylvania anthracite from 1936 to 1938. Shipments by rail to the three principal markets—New York, Pennsylvania, and New Jersey—comprised 83.2 percent of total shipments in 1936, 82.6 percent in 1937, and 82 percent in 1938. However, while the percentage shipped to these markets remained almost the same the quantity dropped from 37,067,743 tons in 1936 to 32,719,986 in 1937 and 26,222,562 in 1938, an over-all decline of 29 percent. During 1938 no foreign coal was imported into these three States. Shipments to Canada fluctuated slightly but held up better during the 3-year period than did those to the domestic market.

Both the tonnage and the method of transporting anthracite to the New England States have varied considerably in the past decade. New England receipts of anthracite of domestic origin totaled 8,556,979 net tons, of which 79 percent was transported by rail, in 1929; 4,809,492 net tons, of which 74 percent was transported by rail, in 1933; and 4,105,004 net tons, of which 85 percent arrived by rail, in 1938. Receipts of anthracite at tidewater in the New England States in 1938, including imports, were 977,170 tons, a decrease of 6.7 percent compared with 1937, and receipts by rail were 3,490,700 tons, a decline of 6 percent.[2]

Loadings at Lake Erie ports dropped 33.2 percent, and receipts at Duluth-Superior were 47.5 percent less than in 1937. Shipments off Lake docks also decreased—at Lake Superior 26.8 percent and at Lake Michigan 11.3 percent.

In March 1938 the Pennsylvania Public Utilities Commission reduced the freight rates to a number of points within the State of Pennsylvania. In the same month a small increase in the rates on interstate shipments of anthracite was allowed by the Interstate Commerce Commission. This increase was extended late in 1938 by the Interstate Commerce Commission to cover intrastate shipments. The so-called motor-compelled freight rates again were extended.

[1] Anthracite Institute.

Incomplete returns on shipments of anthracite in 1938 by destinations, compiled and published monthly by the Pennsylvania Department of Mines, show that about 9 percent of the total shipments move by truck; the corresponding figure in 1937 was 8 percent. Most of the anthracite trucked goes to nearby points. In 1938, about 85 percent of the truck shipments were to destinations in Pennsylvania (60 percent within the anthracite region). As might be expected, New Jersey and New York were the next largest markets, with Delaware, Maryland, and the District of Columbia following in decreasing order. Less than 1,000 tons went by truck to New England and insignificant quantities to Ohio and Canada.

*Stocks.*—At the end of 1938, stocks of anthracite in the hands of railroads, electric-power utilities, and other industrial consumers were 21.4 percent less than at the end of 1937. Railroad stocks dropped 58.4 percent, electric-power-utility stocks 16.1 percent, and stocks of other industrial consumers 11.7 percent. Stocks on upper Lake docks

Digitized by Google

declined 14.8 percent—on Lake Superior 19 percent and on Lake Michigan 10.3 percent. Retail stocks declined 6.2 percent and producers' stocks 32.3 percent.

Recent trends in production and stocks are shown in figure 1.

*Promotional and regulatory activities.*—The Anthracite Institute carried on its usual activities during 1938. Officials of the institute followed closely proposed Pennsylvania legislation to regulate the industry; filed a brief with the Committee for Reciprocity Information requesting that the Canadian duty on United States anthracite be removed; carried on its statistical services; and continued to cooperate with the Bureau of Mines. No change had been made in the import duty by the close of the year, nor had the excise tax been removed. However, the prospect for removal of the excise tax, provided for in the Canadian Trade Agreement which was provisionally scheduled to go into effect January 1939, probably explained the decrease in exports of anthracite to Canada during the latter months of 1938. The tax was removed in April 1939.

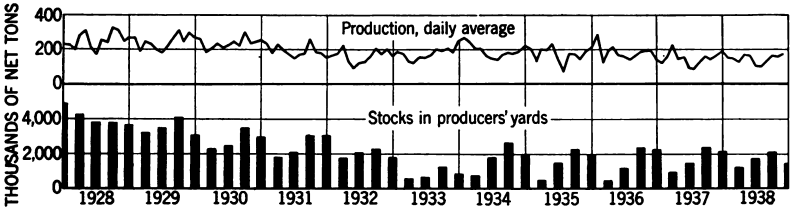

FIGURE 1.—Trends in production and stocks of Pennsylvania anthracite, 1928–38.

Anthracite Industries, Inc., established in the spring of 1936, has become an important agency in developing the market for anthracite and making available to the public higher standards of comfort and convenience in domestic heating. During 1938 Anthracite Industries increased the intensity of its activities. In addition to maintaining first-hand contact with consumers and the trades connected with the industry, its laboratory at Primos, Pa., continued to test for approval anthracite-burning equipment and accessories, and additional schools were conducted to apprise salesmen and others of new developments. Additional showrooms were opened, and the general advertising program was extended.

The first annual anthracite conference, sponsored by Lehigh University was held at Bethlehem, Pa., for 2 days late in April 1938. Papers on reserves, geology, characteristics, and uses of anthracite, description and operation of burning equipment, commercial applications, and merchandising and civic values of anthracite were read and discussed before audiences composed of men interested in all phases of the industry.

The office of the retail solid fuel coordinator of New York City continued its usual duties of policing the New York City market—the largest single anthracite market in the country—against short weight, stolen coal, infractions of coal ordinances, unlicensed truckers, increased freight rates, counterfeit certificates of origin, misrepresentation of coal, and evasion of sales tax and in other details involving the proper operation of the retail industry.

Digitized by Google

In August 1938, following the report and recommendations of the Pennsylvania Anthracite Coal Industry Commission, bills were introduced in the Pennsylvania House providing for production control; licensing mines; fixing sales quotas and minimum and maximum prices at the mines, as well as retail prices; cooperative marketing; creating an anthracite public authority with power to mine, transport, and sell anthracite, to issue bonds, and to have the right of eminent domain; and, finally, creating the Pennsylvania Anthracite Commission as an independent administrative commission. The House adjourned without passing the bills.

Revisions of the State workmen's compensation act by the Pennsylvania Legislature in 1937 went into effect on January 1, 1938, as did a new law that made occupational diseases compensable. Some operators estimated that the cost to the industry for compensation, which in 1937 approximated $2,500,000, would, under the amended act, eventually amount to $7,500,000 a year. As a result, and as permitted by the law, a substantial majority of the producing companies rejected the act as amended but announced that they would voluntarily settle with all claimants on the basis of the law as operated in 1937.

*Technologic developments.*—No outstanding change in the methods of mining anthracite was developed during 1938, either underground or in strip pits. To meet intensive competition both within and without the industry, many minor improvements were made in demonstrated and accepted methods, as is usual under the pressure of decreasing costs, without lowering the grade.

The same can be said of the utilization of anthracite. The design of screw-type automatic stokers was further strengthened and refined, and attention was redirected to the thermal efficiency of furnaces and boilers.

In the field of beneficiation of the raw coal—now occupied by the time-tried screens, jigs, and sand cones with certain auxiliary equipment—a new method was announced by Dupont after several years of intensive laboratory and pilot-plant development which culminated in a commercial demonstration plant at the Weston breaker near Shenandoah, Pa. The process employs the familiar float-and-sink method, but its success is based principally on three factors: Development of suitable halogenated hydrocarbons as parting liquids; discovery of surface-active reagents which in solution greatly reduce loss of the parting liquid by preventing it from adhering to the pieces of anthracite; and assembly of standard equipment to form a continuous, water-sealed operation. As developed to date this process is applicable to the domestic sizes of anthracite. It does not remove the need for preliminary and final screening but is alternative to jigs or sand cones. What permanent place it will occupy in the preparation of anthracite for market cannot be foretold.

*Sources and acknowledgments.*—Annual statistics of the Pennsylvania anthracite-mining industry are prepared from a canvass by mail of all known anthracite operations, including some 400 active producers. About 95 percent of the tonnage is reported directly by producers, and the remaining 5 percent is estimated by personal inspection and collateral evidence. The data furnished by the producers on individual operations are voluntary and confidential, as is customary in the statistical services of the Bureau of Mines.

Digitized by Google

The standard form of report, as developed by the Bureau and its predecessor in mineral statistics, the Geological Survey, provides for data on production, shipments, mine realization of products, mine stocks, plant and equipment, and employment.

In assembling available detailed information free use has been made of the pertinent figures prepared by the Anthracite Institute, the American Association of Railroads, and the Pennsylvania Department of Mines, to all of whom thanks are extended for their cordial and continued cooperation. Thanks are due especially to the producers for reporting so promptly and, in general, so fully upon their 1938 operations, when the year as a whole was so critical for the industry.

Final 1937 figures for employment and number of operations were published on September 10, 1938, as a supplement to Weekly Anthracite-Beehive Coke Report 61 and are incorporated in the present Yearbook. Corresponding 1938 figures are not yet available but will be similarly published when completed and included for permanent record in the next volume of the Yearbook. Advance summaries of final production figures for 1938 were published on June 17, 1939, as a supplement to Weekly Anthracite-Beehive Coke Report 101. They are presented in detail in this chapter.

## PRODUCTION

*By weeks and months.*—The following tables summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from tonnage reports from trade sources and from records of car loadings. The weekly and monthly figures in tables 7 and 8 have been adjusted to the annual total ascertained by direct canvass of the operators.

TABLE 7.—*Estimated weekly production of Pennsylvania anthracite in 1938, in net tons*

[1] Production is estimated from weekly car loadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Does not include an unknown amount of "bootleg" production. In computing the average rates per working day, New Year's, Eight-hour Day (Apr. 1), Memorial Day, Independence Day, Labor Day, Mitchell Day (Oct. 29), Thanksgiving Day, Christmas, and, since the war, Armistice Day, have been counted as holidays. Beginning with 1927, Washington's Birthday is counted as a half holiday. No allowance, however, has been made for church holy days, which are observed by many of the miners. Monthly statistics from 1905 to 1925 will be found in Coal in 1925, pp. 427–428, and from 1926 to 1930 in Coal in 1930, p. 741.

*By regions, fields, and counties.*—The main anthracite region covers an elongated area of about 480 square miles in eastern Pennsylvania, with its longer axis running northeast and southwest. It embraces three subregions as follows, from the northeast to the southwest: The Wyoming region, which covers a single geologic anthracite basin and is about 54 miles long by 6 miles wide at its widest point; the Lehigh region, which comprises the anthracite lands tributary to the Lehigh River that forms its eastern boundary and contains the Eastern Middle field and the portion of the Southern field lying east of Tamaqua; and the Schuylkill region, which consists of the Western Middle field and the portion of the Southern field lying west of Tamaqua.

The area may also be divided into 4 fields, using the grouping of the anthracite geologic basins as a framework, as follows: The Northern field, which is the same as the Wyoming region; the Eastern Middle, or Lehigh field, which consists of a group of at least 10 small basins; the Western Middle field, a single basin about 36 miles long by 4½ miles at its widest point; and the Southern field, also a single basin, about 54 miles long by 6 miles at its widest point, which breaks into a long "fishtail" toward its western ends.

Both classifications (by regions and by fields) are used in the Bureau tables, the former for regional comparative trade statistics and the latter for comparative methods and costs of mining as governed by physical conditions.

In order of magnitude of present production, the Northern field comes first, followed by the Western Middle, the Southern, and the Eastern Middle.

In order of length of life, based on estimated minable reserves, the Southern field comes first, followed by the Western Middle, the Northern, and the Eastern Middle fields.[3]

[1] Value given is value at which coal left possession of producing company, f. o. b. mines, and does not include margins of separately incorporated sales companies.

[2] For purposes of historical comparison and statistical convenience the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

*Fresh-mined and culm-bank coal, breaker, and washery product.*—Anthracite is now produced from three sources—from mines, from old culm banks, and from the rivers that drain the anthracite region. As all three sources contribute to the country's supply, it is important to consider them all to ascertain the total production. No difficulty is experienced in assembling the figures of production by dredges, as these are separate, distinct operations. A statistical detail requiring particular attention is the occasional practice of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. The aggregate annual tonnages of culm-bank coal so treated are shown in the last of the following three tables.

TABLE 12.—*Anthracite produced in 1938, classified as fresh-mined, culm-bank, and river coal and as breaker, washery, and dredge product, by regions, in net tons*

Table 16 reveals an interregional variation in the breaker production of domestic sizes as related to that of steam sizes and to total production, which is of great importance to the profitable operation of individual properties. The Wyoming region in 1938 produced 70 percent domestic sizes and 30 percent steam sizes from a given tonnage of breaker feed; the Lehigh region 65 percent domestic and 35 percent steam sizes; and the Schuylkill region 58.5 percent domestic and 41.5 percent steam sizes. These percentages are relatively constant from year to year. The variation among the regions is due to differences in the physical situation and condition of the anthracite beds. Its effect is shown in receipts from sales, as the average sales realization per ton of total domestic sizes has ranged from $2.77 to $3.57 more than that of total steam sizes over the past 3 years. (See table 17.)

TABLE 16.—*Sizes of Pennsylvania anthracite shipped from breakers, 1936–38, by regions, in percent of total*

[Note that shipments of dredge and washery coal are not included]

| Size of coal | Percent of total shipments | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | Lehigh region | | | Schuylkill region | | | Wyoming region | | |

## PRICES AND AVERAGE SALES REALIZATION

The circular price of company stove coal, f. o. b. mine, ranged from a low of $5.50 in May to $6.40 in November and December and averaged $6.07 for the 12 months, an advance of 1.5 percent over the 1937 average. Company Buckwheat No. 1 remained at $3.50 throughout the year, an increase of 4.2 percent over 1937. The wholesale price of Chestnut, on tracks at destination, ranged from a low of $8.95 in May to a high of $9.71 in November and December and averaged $9.45 for the year, or 0.9 percent above the average price in 1937. The wholesale price of Pea was 0.7 percent less than in 1937. (See Fig. 2.)

In the spring of 1938 the temporary open-price filing agreement, which had gone into effect in January but had not operated satisfactorily, was susperseded by a new agreement to be administered by an agency not identified with the industry. More than 85 percent of the total production is embraced by the agreement, which, however, did not include illicit coal. The new agreement lasted nominally throughout the rest of the year.

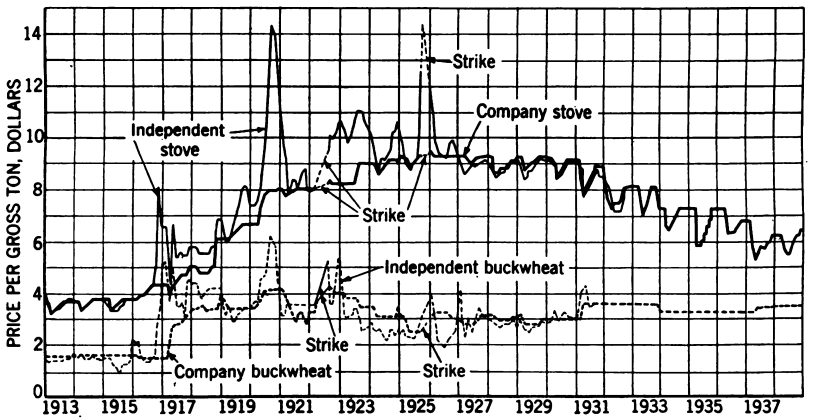

FIGURE 2.—Monthly prices of Pennsylvania anthracite, f. o. b. mine, as quoted by the trade journals, 1913-38. Prices are averages of the range as quoted on the New York market.

The valuation figures in this study represent value at the breaker or washery reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report.

From this it will be seen that when a producing company sells its output to a separately organized sales company (the practice of many, including certain larger producers), the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal in question is placed on the general market. This fact should be borne in mind in considering the variations in value between different regions shown in the tables for the same sizes of coal.

The average sales realization per net ton on breaker shipments rose to $4.16 in 1938 from $4.03 in 1937. There were small increases in the average realization of all sizes except Pea. (See table 17.)

Digitized by Google

If local sales, colliery fuel, washery, and dredge coal are included, the average value per net ton on the total 1938 production is $3.92 compared with $3.81 in 1937. (See table 18.)

TABLE 17.—*Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1936–38, by regions and sizes*

[Value does not include margins of separately incorporated sales companies]

| Size | Lehigh region | | | Schuylkill region | | | Wyoming region | | |

## NUMBER OF OPERATIONS

The total number of active plants reporting increased from 328 in 1936 to 390 in 1937. (See table 19.) Figures for 1938 are not yet available, but indications are that the upward trend continued.

TABLE 19.—*Number of active operations in the Pennsylvania anthracite industry in 1937* [1]

| Region and type of product | Total active plants reporting [2] | Breakers [3] | Other preparation plants [4] | Washeries [5] | Culm banks operated in conjunction with breakers | Dredges | Reporting strip-pit tonnage |
|---|---|---|---|---|---|---|---|
| Lehigh: | | | | | | | |
| Breakers or mines | 35 | 24 | 1 | | 10 | | 25 |
| Dredges | 1 | | 1 | | | 1 | |
| Total Lehigh | 36 | 24 | 2 | | 10 | 1 | 25 |
| Schuylkill: | | | | | | | |
| Breakers or mines | 75 | 38 | 18 | | 11 | | 36 |
| Washeries | 15 | | | 4 | | | 1 |
| Dredges | 27 | | 22 | | | 27 | |
| Total Schuylkill | 117 | 38 | 40 | 4 | 11 | 27 | 37 |
| Wyoming: | | | | | | | |
| Breakers or mines | 219 | 69 | 4 | | 6 | | 27 |

| Total, excluding Sullivan County: | | | | | | | |
| Breakers | 329 | 131 | 23 | | 27 | | 88 |
| Washeries | 27 | | | 6 | | | 1 |
| Dredges | 29 | | 24 | | | 29 | |
| Total | 385 | 131 | 47 | 6 | 27 | 29 | 89 |
| Sullivan County: Breakers | 5 | 5 | | | | | |
| Grand total | 390 | 136 | 47 | 6 | 27 | 29 | 89 |

[1] Figures for 1938 not yet available.
[2] The number of active plants contains numerous duplications, that is, successions known and unknown, and leases and subleases. Each report received which was tabulated for production or for employment has been counted separately.
[3] Equipped to prepare standard sizes of fresh-mined coal.
[4] For preliminary crushing, screening, or cleaning. Usually old breakers are used for this purpose. The number reported for dredges represents reports showing men employed at tipple.
[5] Preparation plant for the sizing and cleaning of culm-bank coal.

## LABOR STATISTICS

According to the Pennsylvania Department of Mines nearly 97,000 men were employed at anthracite mines in 1938. The number employed in 1937, as based on direct reports from operators and including the employees of dredges and strip contractors, was 99,085.

Man-days lost on account of strikes were 42.5 percent greater in 1937 than in 1936. Suspension of work due to strikes and the number of men involved also were greater in 1937 than in 1936. Comparable statistics covering 1938 are not yet available, but there were no widespread labor disputes during the year.

According to the Bureau of Labor Statistics, average weekly earnings ranged from a low of $14.76 in July to a high of $28.94 in June and averaged $23.40 during 1938, or 7.1 percent below the 1937 average. The index of employment (1929 average equals 100) fluctuated between 37.6 in August and 60.0 in February and averaged 13.1 below 1937. The index of pay rolls reached a low of 20.0 in August and a high of 49.7 in June and averaged 18.6 below 1937.

## EQUIPMENT AND METHODS OF MINING

*Mechanical loading.*—Anthracite loaded mechanically underground continued to represent about one-fourth of the total deep-mined production. In 1938 the 10,151,669 tons so loaded were 26.6 percent of the total underground output compared with 25 percent (10,684,000 tons) in 1937 and 24.2 percent (10,827,946 tons) in 1936. The 5-percent decline in tonnage loaded mechanically from 1937 to 1938 was slight compared with the 12.2-percent decrease in quantity loaded by hand and the 11.1-percent drop in total tonnage.

In 1938 sales of both scrapers and conveyors in the Pennsylvania anthracite region were below the 1937 figures. Sales of scrapers declined from 16 in 1937 to 4 in 1938 and of conveyors (including hand-loaded conveyors and conveyors equipped with duckbills or other self-loading heads) from 260 to 241 units. No sales of mobile loading machines were reported.

The number of scrapers in use increased from 539 in 1937 to 545 in 1938, but the number of pit-carloaders and conveyors (with duckbills and other self-loading heads and hand-loaded) dropped from 1,855 to 1,831. These figures include the limited mobile-loading equipment reported in the field, as shown in table 24.

| Wyoming | 137 | 75 | 1,911,149 | 150 | 89 | 1,583,907 |
| Total, excluding Sullivan County | 140 | 78 | 1,952,298 | 150 | 89 | 1,583,907 |
| Sullivan County | 2 | 3 | 32,214 | | 3 | 4,500 |
| Grand total | 142 | 81 | 1,984,512 | 150 | 92 | 1,588,407 |

*Strip-pit mining.*—The percentage of anthracite produced from strip pits compared with fresh-mined anthracite remained virtually constant—11.8 percent in 1938 and 11.9 percent in 1937. The tonnage mined by this method in 1938 fell slightly in the Lehigh region and 25 percent in the Schuylkill region but increased 34 percent in the Wyoming region. Table 27 gives the figures for several years.

TABLE 27.—*Relative growth of Pennsylvania anthracite mined from strip pits, 1915, 1920, 1925, 1930, and 1936–38, in net tons*

| Year | Number of power shovels in use [1] | Quantity mined by stripping | | Percent of fresh-mined total that was stripped | Number of men employed | Average number of days worked |
|---|---|---|---|---|---|---|
| | | Total | Average per shovel | | | |
| 1915 | 57 | 1,121,603 | 19,677 | [2] | [2] | [2] |
| 1920 | 96 | 2,054,441 | 21,400 | 2.5 | [2] | [2] |
| 1925 | 97 | 1,578,478 | 16,273 | 2.7 | [2] | [2] |
| 1930 | 108 | 2,526,288 | 23,484 | 3.7 | [2] | [2] |
| 1936 | 364 | 6,203,267 | 17,042 | 12.2 | 4,667 | 199 |
| 1937 | 351 | 5,696,018 | 16,228 | 11.9 | 4,585 | 184 |
| 1938: | | | | | | |
| Lehigh region | 123 | 1,965,102 | 15,976 | 25.7 | [2] | [2] |
| Schuylkill region | 119 | 2,280,418 | 19,163 | 20.0 | [2] | [2] |
| Wyoming region | 89 | 849,821 | 9,549 | 3.5 | [2] | [2] |
| Total, 1938 [3] | [4] 331 | 5,095,341 | 15,394 | 11.8 | [2] | [2] |

[1] Certain of the equipment reported by stripping contractors may have been counted twice when moved from one small job to another during the year. The amount of such double counting is unknown but presumably is not great.
[2] Data not available.
[3] There was no strip-pit mining in Sullivan County during 1938.
[4] Incudes 102 gasoline, 22 steam, 64 electric, 133 Diesel, and 10 other types of shovels.

| | 29 | 760,474 | 842,052 | 34 | 571,024 | 570,579 |

TABLE 29.—*Average receipts per net ton on all dredge coal sold, 1933–38*

| Year | Average receipts | Year | Average receipts |
|---|---|---|---|
| 1933 | $0.84 | 1936 | $1.06 |
| 1934 | .98 | 1937 | 1.11 |
| 1935 | .88 | 1938 | 1.00 |

## FOREIGN TRADE [4]

*Imports.*—Imports of anthracite declined from 395,737 tons in 1937 to 362,895 in 1938, or 8.3 percent. In 1938 imports were equivalent to 19 percent of exports compared with 21 percent in 1937.

TABLE 30.—*Anthracite imported for consumption in the United States, 1937–38, by countries, in net tons*

| Country | 1937 | 1938 | Country | 1937 | 1938 |

*The Canadian market.*—In 1937 and 1938, 56 and 53 percent, respectively, of Canadian imports of anthracite came from the United States. Not since 1932 had Pennsylvania anthracite occupied so favorable a position over competitors in the Canadian market. Bituminous coal imported into Canada from the United States in 1938 maintained its usual high percentage, but there was a marked decline in tonnage from 1937.

Complete data on fuel and power consumption in Canada in 1938 are not available, but indications point to a decline in coal and lignite production and a decided drop in imports compared to 1937.

Digitized by Google

The trend toward increased consumption of natural gas, fuel oils, and water power in recent years was continued in 1937 and 1938. The total mineral fuels and water power, in terms of coal, available in 1937 will considerably exceed the figure for 1936 [5] and may reach that for the peak year 1929, but a marked decrease in available coal in 1938 may depress the aggregate consumption of these power resources for the country to the 1928 and 1936 levels, or to the equivalent of about 50,000,000 tons of coal. The following table gives data on the coal and coke industry and trade of Canada in 1937 and 1938.

TABLE 34.—*Coal and coke industry and foreign trade of Canada, 1937–38* [1]

[1] Coal statistics for 1937 are from Coal Statistics for Canada for the Calendar Year 1937, p. 29, Table 29. Coal statistics for 1938 are from Quarterly Coal and Coke Statistics for Canada, October–December 1938, pp. 4, 5, and 14. Coke statistics are from Quarterly Coal and Coke Statistics, October–December 1937, p. 13, and October–December 1938, pp. 14 and 16. Canadian coal charged to ovens in 1937, 1,162,247 tons; 1938, 1,064,302 tons. Imported coal charged to ovens in 1937, 2,415,095 tons; 1938, 2,215,469 tons.

Preliminary figures, in terms of coal, show that Canadian consumption of natural gas increased from 1,125,000 tons in 1936 to 1,295,000 tons in 1937 and 1,326,000 tons in 1938, and that of fuel and gas oils from 3,259,000 tons in 1936 to 3,539,000 tons in 1937.

Apparently there is a wide variation in the prices paid by Canadian importers for anthracite. The invoice value is based on the fair market value or price of anthracite sold for home consumption in the principal markets of the country of origin at the time shipment is made, but the value must not be less than the price to jobbers and wholesalers generally nor less than the actual cost of production at the time of shipment, plus a reasonable advance for cost of selling and profit.

In 1937 and 1938, respectively, the price per net ton for domestic sizes, except Pea, of anthracite from Great Britain was reported as $5.37 and $5.83; from the United States, $5.62 and $5.74; from Germany, $4.27 and $4.33; and from the U. S. S. R., $2.37 and $4.54.[6]

As the United States is the source of virtually all the bituminous coal imported into Canada the extent of Canadian subventions in aid of its coal industry is of interest. The tonnage of Canadian coal

[5] Minerals Yearbook. 1938, p. 754.

moved under assisted (railroad) rates amounted to 146,000 net tons in 1928, reached 1,149,000 tons in 1932, and was 2,182,000, 2,356,000, and 2,637,000 net tons in 1935, 1936, and 1937. Of the 1937 tonnage, 1,909,000 tons came from Nova Scotia and most of the remainder from Alberta, Saskatchewan, and British Columbia.[7]

It is understood that a further increase in subventions was granted the Nova Scotia industry late in 1938, in which year the cost of the subsidies totaled $1,858,000.

| Byproduct coke ovens owned by city-gas companies | 908 |

The coke industry shared the general business recession of 1938. Outstanding in the record of coke production during the year was the fact that for the first time since 1932 output failed to increase over that of the preceding year.

Total output from byproduct and beehive ovens in 1938 fell from 52,375,469 to 32,633,304 tons, a decrease of 19,742,165 tons or nearly 38 percent from 1937. Compared with the peak year 1929 when output totaled 59,883,845 tons, the decrease was more than 45 percent.

Of the total production in 1938 byproduct ovens contributed 31,795,892 tons (97.4 percent) and beehive ovens 837,412 tons (2.6 percent). At byproduct plants output decreased from 49,210,748 tons in 1937 to 31,795,892 in 1938, a loss of 17,414,856 tons (35.4 percent). The bulk of this decline occurred at "furnace" coke plants, where output, reflecting the drastic curtailment at blast-furnace operations, dropped 43 percent. At merchant plants (including public utility plants operating byproduct-coke ovens), output declined only 15 percent. The difference in the rate of decrease is explained by the difference in stability of the markets supplied by the two classes of plants. The greater part of the output of furnace plants is used in blast furnaces, which were affected much more by the industrial recession than the coke industry as a whole.

The trend of activity in the coke industry during 1938 was represented by two distinctly opposite movements. The first 6 months were characterized by continuation of the sharp downward curve that began in September 1937 and terminated with a low production point of 2,116,300 tons in June 1938; a definite upward movement followed,

[1] Data for byproduct coke in 1938 are preliminary: for beehive coke they are final. Detailed statistics with final revisions will be released later.

Digitized by Google

and output climbed steadily to a high point of 3,438,400 tons in December. Production in the latter half of 1938 exceeded that of the first half by more than 2,000,000 tons.

An adequate supply of byproduct coke for furnace use checked the beehive-coke "boomlet" that flourished throughout 1937 until the last 2 months of the year. Beginning with a production of 114,100 tons in January 1938 and ending with an output of only 75,600 tons in December the yearly total of 837,400 tons decreased 74 percent from 1937.

Stocks of byproduct coke, which ordinarily rise as production falls, were up 1,090,374 tons (43 percent) by the end of the year; at merchant plants the increase was 57 percent, while at furnace plants stock piles rose only 24 percent. At the average daily rate of production throughout the year reserves at the end of December would have sufficed for a little more than 41 days. Supplies of coking coal in stock at byproduct plants showed only seasonal variation during the year, the quantity on hand at the end of the year—7,462,163 tons—being less than 3 percent over the 1937 total.

Imports for consumption declined 53 percent and exports 8 percent, the indicated consumption of all coke being 39 percent less than in 1937.

Shipments of all coke by rail throughout the country dropped 46 percent below the 1937 level, while the volume of river commerce via the Allegheny River decreased 47 percent, via the Monongahela River 31 percent, and via the Ohio River 17 percent.

A selected list of retail dealers reported that deliveries were 40 percent under 1937, while stocks at the same yards decreased 22 percent.

Circular prices for the various grades of coke, quoted by trade journals, showed a rising tendency in general, the only important exception being a decline in the asking price of Connellsville furnace coke. Actual reports received from operators of beehive coke plants indicate a slight increase in total sales-realization averages.

In the field of byproducts, the only statistics available for 1938 cover ammonia and benzol; production data for these commodities indicate decreases of 30 and 39 percent, respectively, from 1937.

## SCOPE OF REPORT

Owing to reduction in the funds appropriated for collection by the Bureau of Mines of statistical and economic data relating to the fuel industries it has been impossible to complete the 1938 annual canvass of the byproduct coke industry in time to publish the final data in the present Minerals Yearbook. In the majority of instances the preliminary data presented were furnished currently by the coke operators and will vary within a fraction of 1 percent from the final detailed statistics. The statistics pertaining to the beehive coke industry in this issue are complete and final. Final detailed statistics of both branches of the industry will be distributed in mimeographed form as soon as available and will be incorporated with 1939 data in the next volume of the Yearbook. If not readily found any derivative figures carried in earlier reports will be furnished by the Bureau upon application.

In the United States coke is produced by a group of four different industries. In addition to that manufactured in the familiar beehive and byproduct ovens coke is obtained in the refining of petroleum, in the manufacture of coal gas, and in the refining of tar. Within the last few years, also, production of a smokeless fuel by low-temperature carbonization of coal has been established commercially in the United States. The coke produced by each of these processes, however, varies greatly in character, and the problems affecting each of the industries are separate and distinct.

In 1938 about 1,602,200 tons of petroleum coke were produced compared with an output of 1,306,600 tons in 1937; approximately 918,400 tons of gas-house coke were made, a slight decrease from the 1937 output of 941,000 tons. The manufacture of coke from coal-tar pitch has been established on a commercial basis, but the tonnage produced is relatively small; in fact, the production in 1937—the latest year for which figures are available—amounted to only 181,495 tons, as reported by the United States Tariff Commission. None of these other kinds of coke are discussed in this report. Only coke from byproduct and beehive ovens is adapted to blast-furnace and foundry uses, which consume the bulk of all the coke produced. Practically, therefore, the coke trade is concerned only with byproduct and beehive coke, and the statistics of this report are confined to these two types.

Digitized by Google

For reasons explained in a later section the statistics of byproduct coke in this chapter cover the operations of all byproduct coke ovens, including those installed and operated by public utilities engaged primarily in manufacturing gas for city supply.

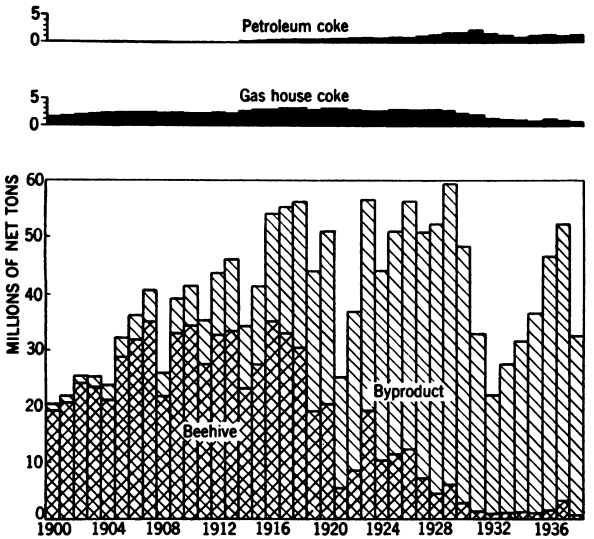

FIGURE 2.—Production of petroleum coke, gas-house coke, and beehive and byproduct coke in the United States, 1900–38. No figures on production of petroleum coke are available before 1914, when the production was 213,777 tons.

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds, and unless otherwise specified that unit is employed throughout this report.

## PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The terms "furnace" and "merchant" operators originated in the Connellsville beehive coke trade. As the name implies the beehive-furnace interests are those affiliated with the producers of iron and steel whose output does not ordinarily enter the open market. There are, however, a number of byproduct plants financially affiliated with iron furnaces, in which the bulk of the product is nevertheless foundry and domestic coke that must be sold on the competitive market. Inasmuch as the beehive coke trade has dwindled during the past decade to a position of little significance in the coke industry (in 1938 supplying only 2.6 percent of the total production) the statistics presented in the two following tables cover byproduct coke only.

A "furnace" plant is herein defined as one that has for its main business the production of furnace coke and that has an assured outlet for such coke either through financial affiliation with or direct ownership by an ironworks, or through long-time contracts. Under this definition the class designated as "other" plants includes a few plants affiliated with local iron furnaces but producing much more coke than the furnaces can absorb and therefore depending chiefly on the foundry and domestic trade or on merchant sales of furnace coke. It also includes merchant producers of furnace coke who have to sell their output on the competitive market; the plants affiliated with alkali works; and, in addition, a number of plants that, although not public utilities, were constructed primarily to supply city gas and that must sell their coke where they can for domestic and industrial as well as metallurgical use.

In 1938, 43 furnace plants produced 20,679,091 tons of byproduct coke and 40 "other" plants produced 11,116,801 tons. The relative proportion furnished by furnace plants has remained fairly constant except in the years of iron and steel depression. Thus, in 1913 and again in 1918, furnace plants produced approximately 73 percent of the total byproduct coke output. In 1932, a year of great steel depression, the proportion fell to 54 percent; it rose to 73 percent in 1937 and fell again to 65 percent in 1938.

TABLE 7.—*Number and production of byproduct coke plants connected with iron furnaces and of other byproduct plants, 1913, 1918, and 1936–38*

| Year | Number of active plants | | Coke produced (net tons) | | Percent of production | |
|---|---|---|---|---|---|---|
| | Furnace plants | Other plants | Furnace plants | Other plants | Furnace plants | Other plants |
| 1913 | 20 | 16 | 9,277,832 | 3,436,868 | 73.0 | 27.0 |
| 1918 | 36 | 24 | 19,220,342 | 6,777,238 | 73.9 | 26.1 |
| 1936 | 42 | 43 | 32,076,089 | 12,493,032 | 72.0 | 28.0 |
| 1937 | 43 | 42 | 36,134,209 | 13,076,539 | 73.4 | 26.6 |
| 1938 [1] | 43 | 40 | 20,679,091 | 11,116,801 | 65.0 | 35.0 |

## PRODUCTION BY STATES AND DISTRICTS

All 21 States that produced byproduct coke in 1938 shared the decreased output, the percentage of decrease being higher in those States dominated by furnace interests. Thus, Colorado showed the highest relative decrease—61 percent—followed by Pennsylvania with a decline of 48 percent, Indiana with 47 percent, Ohio with 45 percent, and Illinois with 42 percent. Other rates of decrease ranged from 0.2 percent in Massachusetts (a "merchant" State) to 27 percent in Maryland.

In rank of producing importance the position of Pennsylvania remains unchallenged. In 1938 the State contributed 22 percent of the byproduct coke total, 58 percent of the beehive, and 23 percent of all coke produced in the United States. Not only is Pennsylvania the principal coke-producing State, but large quantities of her celebrated coking coals are shipped annually to other States for use in byproduct ovens. The famous Pittsburgh bed, underlying the Pittsburgh, Connellsville, and adjacent fields, is probably the largest repository of high-grade coking coal in the world.

## NUMBER AND TYPE OF OVENS

In the byproduct branch of the coke industry 202 new byproduct ovens were completed and put into operation during 1938; of these 41 were in Colorado, 12 in Kentucky, 65 in Michigan, and 84 in Ohio. One new furnace plant was added to the active list, operations beginning in October 1938. At the close of the year 126 ovens still were under construction, and 182 had been abandoned, the total in existence at the 88 plants being about 12,650. Four of the 88 plants were idle throughout the year, 7 were out of blast at the close of December, and a few others operated on a part-time basis.

Beehive coke ovens have been dismantled steadily during the past 3 decades and in 1937 were exceeded in number by byproduct ovens for the first time. In 1910 there were 100,362 beehive ovens; in 1920, 75,298; and in 1930, 23,907; in 1938, only 10,816 remained. Byproduct ovens during the same period rose from 4,078 in 1910 to 10,881 in 1920, and to 12,831 in 1930, but dropped to 12,650 in 1938, the net change during the past 8 years being slight. There is of course no basis of comparison between a byproduct and a beehive oven with respect to operating capacity, but the figures show the changing trend of coking practices.

The 72 beehive coke plants in existence at the close of 1938 comprised 10,816 ovens. However, only 38 plants with a total of 5,453 ovens were active. In 1938, for the first time, the Bureau of Mines asked beehive operators to report the average number of ovens active during each month of 1938. Responses to this inquiry indicate that the highest number operating in any month (January) was 2,729 ovens and the lowest (October) was 1,519—an unweighted average for the year of 1,846 ovens.

## CAPACITY OF BYPRODUCT OVENS

The reported maximum capacity of the byproduct ovens in existence is seldom if ever attained for various practical reasons that may be due to operating, economic, or labor conditions. It has been stated that the efficient life of a coke oven is limited to 20 years, as high radiation losses occur after that period; other claims have been made that ovens built 25 years ago still are capable of efficient operation. Had it not been for the depression years much replacement building would have been done. The closing down of ovens over an extended period added to their life and made replacement unnecessary in many instances.

The maximum daily capacity of the 88 byproduct coke plants in existence December 31, 1938, was 174,690 tons, an increase of about 1.6 percent compared with that reported for 87 plants at the end of 1937. The daily capacity at the 42 merchant plants was 43,290 tons, an average of 1,031 tons per plant, while at the 46 furnace plants the capacity was 131,400 tons (2,857 tons per plant), the furnace plants as a rule carrying larger batteries of ovens.

Production of byproduct coke in 1938 was 51 percent of the calculated capacity of all by product ovens compared with 79 percent in 1937 and 91 percent in the peak year 1929. Furnace plants operated at only 44 percent of capacity, while merchant plants operated at 71 percent.

## QUANTITY AND COST OF COAL CHARGED

Although the quantity of coal used in the manufacture of coke has fluctuated widely in the past decade the proportion of total output of bituminous coal carbonized each year has remained remarkably constant, ranging from 10.3 to 16.2 percent, with an average of 13.7 percent, for the 5-year period 1929–33, inclusive, and from 12.8 to 16.8 percent, with an average of 14.5 percent, for 1934–38. In 1938 the proportion fell slightly below the average for the 10-year period (14.1 percent). In that year coke ovens consumed 46,352,700 tons or only 13.5 percent of the total output of bituminous coal. Of this quantity 44,992,800 tons were used in byproduct ovens.

The cost of coal constitutes the chief item of expense in the manufacture of coke. In 1937 the cost of raw coal f. o. b. ovens ranged from $1.86 in Virginia, where all the coke is made in beehive ovens at the mines, to $5.24 in Minnesota, where the cost includes heavy freight charges from distant mines.

The average cost of coal in byproduct ovens in 1937 was $3.74 a ton, and the cost of the coal equivalent of 1 ton of merchantable coke was $5.27. The corresponding figures for beehive coke were $2.01 and $3.14, respectively. In 1938 the cost of the coal consumed at beehive ovens had risen to $2.05, and the cost of the coal equivalent per ton of coke rose in turn to $3.32.

The Bureau of Mines has been determining the expanding properties of coal, particularly of samples received in connection with the survey of gas- and coke-making properties of American coals. A recent

Digitized by Google

report of investigations on the expansion of coal during coking [2] will be of value to readers interested in the technology of the coke industry.

## PREPARATION AND SOURCE OF COAL

In Alabama, Colorado, Tennessee, and Washington and certain parts of Illinois, New York, Ohio, and Pennsylvania the coal used for coking is washed before it is charged in the ovens. The washing sometimes is done by the coal operator at the mine and sometimes by the coke producer at the plant. For the country as a whole in 1937, 25 percent of the coal used in byproduct ovens and 18 percent of that in beehive ovens was washed before charging. In 1938 operators of beehive plants reported that 427,858 tons—31 percent of a total of 1,359,876 tons—were washed before coking.

TABLE 21.—*Washed and unwashed coal used in the manufacture of byproduct and beehive coke, by States in which used, in 1937, in net tons* [1]

| State | Washed | Unwashed | Total |
|---|---|---|---|
| Byproduct ovens: | | | |
| Alabama | 5,288,498 | 597,700 | 5,886,198 |
| Colorado | 722,865 | | 722,865 |
| Illinois | 348,648 | 3,902,368 | 4,251,016 |
| Indiana | | 7,588,989 | 7,588,989 |
| Maryland | | 2,084,471 | 2,084,471 |
| Massachusetts | | 1,615,444 | 1,615,444 |
| Michigan | | 3,213,934 | 3,213,934 |
| Minnesota | | 1,002,812 | 1,002,812 |
| New Jersey | | 1,434,022 | 1,434,022 |
| New York | 942,110 | 5,952,222 | 6,894,332 |
| Ohio | 1,385,530 | 8,023,657 | 9,409,187 |
| Pennsylvania | 8,326,663 | 11,580,441 | 19,907,104 |
| Tennessee | 129,635 | | 129,635 |
| Utah | | 264,070 | 264,070 |
| Washington | 26,118 | | 26,118 |
| West Virginia | 59,727 | 2,512,602 | 2,572,329 |
| Connecticut, Kentucky, Missouri, Rhode Island, and Wisconsin | 27,021 | 2,545,826 | 2,572,847 |
| Total byproduct | 17,256,815 | 52,318,558 | 69,575.373 |
| At merchant plants | 1,650,160 | 16,551,650 | 18,201,810 |
| At furnace plants | 15,606,655 | 35,766,908 | 51,373,563 |
| Beehive ovens: | | | |
| Colorado | 115,278 | | 115,278 |
| Pennsylvania | 730,707 | 3,176,047 | 3,906,754 |
| Tennessee | 27,803 | | 27,803 |
| Utah | | 12,271 | 12,271 |
| Virginia | | 412,192 | 412,192 |
| Washington | | | |
| West Virginia | | 452,526 | 452,526 |
| Total beehive | 873,788 | 4,053,036 | 4,926,824 |

[1] Figures for 1938 not yet available.

The Appalachian fields remain the principal source of byproduct coal, although it is interesting to note that in 1937 small amounts were drawn from Illinois and Ohio. States that are not rated as

Digitized by Google

producers of coking coal; and larger amounts came from the western portion of the United States (Colorado, New Mexico, Utah, and Washington). The total supplies from these four Western States amounted to 1,030,755 tons—less than 2 percent of the total.

Pennsylvania headed the list of States in volume of supplies with 43 percent of the total, followed by West Virginia with 35 percent, Kentucky with 11 percent, and Alabama with 8 percent. Other States producing coking coal supplied less than a million tons each.

TABLE 22.—*Coal used in manufacture of byproduct coke in 1937, by fields of origin, in net tons* [1]

[Based upon detailed reports from each coke plant. The difference between these totals and those shown in tables 1, 9, 19, etc., is due to change in stock, loss of weight in handling, and the fact that these sometimes represent purchases during the year rather than actual consumption]

| State and district where coal was produced | Total used | States where coal was consumed, in order of importance |
|---|---|---|
| Alabama | 5,802,069 | Alabama. |
| Colorado: | | |
| Canon, Crested Butte, and Walsen | 135,155 | Colorado. |
| Trinidad | 578,420 | Do. |
| Illinois: Franklin County | 103,663 | Illinois. |
| Kentucky: | | |
| Eastern Kentucky: | | |
| Elkhorn (including Hazard) | 2,013,310 | Indiana, New York, Ohio, Kentucky, Michigan, Missouri, New Jersey, Minnesota, and Illinois. |
| Harlan | 3,484,375 | Indiana, Illinois, Michigan, Minnesota, and New York. |
| Kenova-Thacker [2] | 1,762,589 | Michigan, Ohio, Wisconsin, Massachusetts, Minnesota, West Virginia, and Kentucky. |
| Miscellaneous | 638,800 | Indiana. |
| New Mexico: Raton-Trinidad | 9,290 | Colorado. |
| Ohio | 503 | Ohio. |
| Pennsylvania: | | |
| Central Pennsylvania: | | |
| High volatile | 53,714 | New York. |
| Medium volatile | 861,641 | New York and Pennsylvania. |
| Low volatile | 1,458,864 | Pennsylvania, Maryland, New York, and West Virginia. |
| Connellsville | 15,167,424 | Pennsylvania, Ohio, West Virginia, New York, Illinois, Minnesota, Michigan, and New Jersey. |
| Freeport | 1,555,926 | West Virginia, New York, Ohio, Michigan, and Pennsylvania. |
| Pittsburgh | 9,154,109 | Pennsylvania, New York, Ohio, Michigan, Illinois, Minnesota, Wisconsin, and Indiana. |
| Somerset | 617,358 | Pennsylvania, West Virginia, and Ohio. |
| Westmoreland | 1,364,765 | Pennsylvania, Maryland, and New York. |
| Miscellaneous | 8,168 | Pennsylvania. |
| Tennessee | 110,390 | Tennessee. |
| Utah: Carbon County | 285,430 | Utah. |
| Virginia: [2 3] | | |
| Southwestern Virginia | 281,396 | New Jersey and New York. |
| Washington: Pierce County | 22,460 | Washington. |
| West Virginia: [2 3] | | |
| Coal and coke [4] | 150,226 | Pennsylvania and Minnesota. |
| Kanawha and Logan (including Coal River). | 8,396,995 | Indiana, Illinois, Massachusetts, Ohio, New York, New Jersey, West Virginia, Connecticut, Michigan, Wisconsin, Pennsylvania, Minnesota, Rhode Island, Kentucky, and Missouri. |
| New River and Winding Gulf | 2,114,150 | Massachusetts, New York, Illinois, New Jersey, Missouri, Rhode Island, Pennsylvania, Minnesota, Kentucky, Indiana, Michigan, and Ohio. |
| Northern | 2,827,290 | Pennsylvania, Maryland, Ohio, West Virginia, Illinois, and New York. |
| Pocahontas [3] | 10,969,509 | Indiana, Ohio, Illinois, New York, Michigan, Maryland, Pennsylvania, Wisconsin, Minnesota, West Virginia, Kentucky, Connecticut, Alabama, Massachusetts, and Tennessee. |
| Webster-Gauley | 249,988 | Pennsylvania. |
| | 70,177,977 | |

[1] Figures for 1938 not yet available.
[2] Tonnage from the extension of Thacker field in Virginia and West Virginia is included under Kenova-Thacker (Kentucky).
[3] Coal from the extension of the Pocahontas field in Tazwell County, Va., is included under West Virginia (Pocahontas).
[4] Includes tonnage from all of U. S. Coal Commission field 24a-b-c except Webster-Gauley.

## CONSUMPTION OF COKE

Allowing for imports and exports and for changes in producers' stocks the indicated consumption of coke in 1938 was 31,222,635 tons. Of this amount 16,995,777 tons (about 54 percent of the total) were, according to figures compiled by the American Iron and Steel Institute, consumed by blast furnaces in the manufacture of pig iron and ferro-alloys. The remainder—14,226,858 tons (46 percent)—was used in foundries, in smelting the nonferrous metals, in the manufacture of water gas, in miscellaneous other industrial uses, and for domestic heating.

The consumption of coke for purposes other than iron manufacture has increased notably in recent years. In 1913 the total used for nonfurnace purposes was only 18 percent; by 1930 it had risen to 30 percent and by 1938 to 46 percent.

The noteworthy improvement in efficiency of fuel utilization in blast-furnace operations during recent years is shown clearly by the fact that the quantity of coking coal required to make 1 gross ton of pig iron declined from an average of 3,637.2 pounds in 1913 to 2,865.1 in 1938.

TABLE 26.—*Coke consumed in manufacture of pig iron and for other purposes, 1913, 1918, and 1936–38, in net tons*

| Year | Total production of coke | Imports | Exports | Net changes in stocks | Indicated United States consumption [1] | Consumed by iron furnaces [2] | | Remainder consumed in other ways | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | | Quantity | Percent | Quantity | Percent |
| 1913 | 46,299,530 | 101,212 | 987,395 | [3] | 45,413,347 | 37,192,287 | 81.9 | 8,221,060 | 18.1 |

## FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

The terms "furnace coke" and "foundry coke," as used in the trade, refer to the size and grade of the coke as well as to the use for which it may be intended. Byproduct furnace coke ordinarily is run-of-oven coke from which the breeze and all small coke less than, say, three-fourths inch in diameter have been removed. Byproduct foundry coke ordinarily is a blocky coke of maximum size much greater than that of furnace coke, from which all sizes under 2½ to 3 inches are screened out. Coke of smaller size than furnace or foundry (exclusive, however, of breeze) often is called domestic coke. It may result from the screening of foundry or furnace coke or, where the principal demand is for domestic coke, may be obtained by crushing the larger fragments. Other special sizes and grades may be prepared for special purposes. Thus, not all furnace coke finds its way to blast furnaces or all foundry coke to iron foundries proper, for either grade may be purchased by other classes of consumers.

Coke enters the domestic fuel market mainly under two conditions: (1) In or near areas of surplus metallurgical coke production and (2) in localities where the manufacture and distribution of large quantities of city gas results in the production of correspondingly large quantities of coke. Since this fuel is, on the average, not transported as far as coal, its consumption for domestic purposes tends to be localized in regions near the centers of production. In recent years the majority of the coke operators have reported that their plants are equipped to screen and size coke for domestic use.

In years of heavy blast-furnace activity (such as 1937) the coke plants owned by or having contracts with steel interests concentrate on the production of furnace coke, and less is available for domestic and industrial use. When the reverse is true, as in 1938, the surplus metallurgical coke is thrown on the open market, sometimes at a lower-than-cost price. Thus, in 1933 only 54 percent of the total amount sold or used at coke plants was for blast-furnace use, and 43 percent was for domestic and other industrial use. In 1937 furnace coke at byproduct plants constituted 77 percent of the total, and 19 percent went for domestic and other industrial purposes. At beehive plants in the same year 65 percent was furnace and 24 percent domestic and other industrial. For the year 1938 only 37 percent of beehive coke went to blast furnaces, while 44 percent was sold for general domestic and industrial purposes. Complete figures are not yet available for the byproduct coke industry in 1938. It is known, however, that about 7,100,000 tons of coke were sold for domestic purposes in that year, a decrease of only 9 percent over 1937 compared with a general decrease of 35 percent in the total production of byproduct coke.

## STOCKS OF COKE AND COKING COAL

With the growth of the domestic coke trade the problem of storing coke at the producers' plants has become increasingly important, especially during the spring and summer.

On January 1, 1938, byproduct coke in stock amounted to 2,519,320 tons, of which 1,878,652 tons (75 percent,) were for domestic and general industrial use. By the end of the year total byproduct stocks had risen to 3,609,694 tons, an increase of 43 percent. Merchant plants, which supply the bulk of the domestic trade, increased their stock piles 57 percent during 1938, rising almost steadily from a low point of 786,710 tons on April 1, 1937 to a high of 2,438,396 tons on December 1, 1938. Furnace plants ordinarily carry relatively steady stocks, although during the same period they fluctuated between 467,322 and 1,460,435, ending at 1,306,719 tons. Beehive plants as a rule carry but few stocks on hand due in part to sporadic activity of the ovens during the year. At the close of 1938 there were 44,931 tons of coke in inventory, of which 29,367 tons were for domestic use.

TABLE 30.—*Stocks of furnace, foundry, and domestic coke and of breeze on January 1, 1938, by States, in net tons*

[Based on complete reports from all producers]

| State | Furnace | Foundry | Domestic and other | Total coke | Breeze |
|---|---|---|---|---|---|
| Byproduct plants: | | | | | |
| Alabama | 191,197 | 4,829 | 49,322 | 245,348 | 29,841 |
| Colorado | 1,288 | 177 | 3,828 | 5,293 | |

For the first time in this chapter the Bureau of Mines presents statistics showing stocks of bituminous coal for coking at byproduct coke plants.

Stocks of bituminous coal follow closely the fluctuations in the trend of monthly coke production. In 1938 a low point was reached in May, when 4,867,332 tons were on hand; the peak occurred in December, with 7,462,163 tons in stock. The low month in coke production was June and the high month December.

TABLE 33.—*Stocks of bituminous coal at byproduct coke plants at end of each month, 1935–38*

| Month | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|
| January | 5,014,012 | 4,640,021 | 8,030,871 | 6,469,457 |
| February | 4,989,425 | 3,844,535 | 8,687,389 | 5,822,943 |

## VALUE AND PRICE

Reference has been made in previous chapters to the varying accounting practices of coke operators financially affiliated with iron and steel plants, by which the coke sometimes is charged to the furnace department at cost and sometimes at a price that includes a percentage of profit or at the prevailing market price.

According to trade journal quotations published currently during 1938, prices on byproduct foundry coke advanced in five markets, decreased in five other markets, and remained stationary at Buffalo, N. Y. The increases ranged from 12 cents per ton in New England to 24 cents at Philadelphia, and decreases ranged from 2 cents at Indianapolis to 24 cents at Detroit. Connellsville prices, which have until recent years been regarded as basic reference prices for the entire industry, declined 6 cents for foundry coke and 43 cents for furnace coke.

Price cutting, long-time contracts, and other factors, however, materially affect the prices at which coke operators actually dispose of coke on the open market. No data are available at this time to show the actual receipts from coke sales at byproduct plants during 1938. Beehive coke operators have, however, reported the following average values obtained for their product: Furnace coke (merchant sales) $4.06, a decrease of 2 cents per ton from 1937; foundry coke $4.91, a decrease of 20 cents; for manufacture of water gas $3.77, a decrease of 25 cents; for other industrial use $4.42, a decrease of 1 cent; and for domestic use $3.52, a decrease of 37 cents. Total value of the 873,412 tons produced, including all coke used or sold for blast-furnace purposes, was $3,702,795, an average value of $4.42 per ton. At the same time the cost of the coal consumed in beehive ovens rose to $2.05 in 1938, an increase of 4 cents per ton from 1937.

TABLE 34.—*Average receipts per net ton for coke sold in 1937, by States* [1]

| State | Byproduct | | | | Beehive | | | |

## EXPORTS AND IMPORTS[2]

Exports of coke from the United States totaled 486,571 tons valued at $3,035,105 in 1938, a decrease of 40,112 tons from the 1937 total of 526,683 tons. It is worthy of note that while United States production declined 38 percent, exports to foreign countries dropped less than 8 percent. As usual, the principal export movement was to Canada, which received 461,310 tons (95 percent of the total) the bulk going through the gateways of Buffalo and Michigan. Outside of Canada the export market for American coke is small, although 6,013 tons were shipped to France and 5,880 tons to Switzerland in 1938.

Imports of coke supply an insignificant part of the requirements of the country and are a factor in the home market only in restricted localities. In 1938, 135,240 tons were received in the United States, supplied by only four countries—Canada, Belgium, Germany, and the United Kingdom—in order of importance.

## WORLD PRODUCTION

Although data on world production of coke in 1938 are incomplete, figures are available to show the output of most of the principal producing countries. For the first time since 1921 the United States relinquished its position as the leading coke producer of the world. Germany led in 1938 with an output of 43,510,956 metric tons, followed by the United States, U. S. S. R., and Great Britain in the order named. World production of coke gained 22 percent in the decade 1928–37, most of the expansion occurring in U. S. S. R., which increased its production nearly fourfold during this period.

TABLE 42.—*Coke produced in principal countries, 1929 and 1935–38, in metric tons* [1]

[1] Gas-house coke is not included.
[2] Data not available.
[3] Estimate included in total.
[4] Beginning with March 1935 production of the Saar is included with that of Germany.
[5] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was as follows: 1935, 12,175,443 tons; 1936, 12,935,933 tons; 1937, 13,150,928 tons.
[6] Figures for 1929 represent "hard" and "soft" coke made at collieries only (73,616 tons of "hard" coke and 769,888 tons of "soft" coke). Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1935, 904,840 tons; 1936, 932,534 tons; 1937, 850,581 tons.

## COKE-OVEN BYPRODUCTS

The statistics in the following tables are confined to the major products obtained in high-temperature byproduct ovens. These products fall into five general groups, some of which are further subdivided. They are (1) gas, by far the most valuable byproduct, followed by (2) light oil and derivatives, (3) tar, (4) ammonia, and (5) miscellaneous products. In recent years an increasing number of operators have installed equipment at their plants for making tar derivatives on the premises. The sales value of such derivatives during 1937 amounted to $2,944,439, including phenol and sodium phenolate (except for phenol and tar acids produced at Clairton, Pa.), and the tar that went into the distilling of these products totaled 88,588,133 gallons, reported from eight plants. Total sales value of all byproducts in 1937 was $132,124,838, more than half the value of the coke production. If to this amount is added a value for the tar used by the producer ($10,490,075), and the value of the breeze production ($7,954,608), the ratio of the value of byproducts to the value of coke produced becomes about 3 to 5.

Complete statistics are not available at this time covering production and sales of byproducts during 1938; however, monthly reports received currently from coke operators throughout 1938 indicate a production of 873,405,000 pounds of ammonium sulfate and 44,025,000 pounds of ammonia liquor ($NH_3$ content), decreases of 32 and 19 percent, respectively, from 1937. The bulk of the ammonium sulfate is recovered at furnace plants, where coke production decreased 43 percent, while ammonia liquor is produced mainly at merchant plants, where the coke output dropped 15 percent. Benzol output (crude and refined plus motor benzol), as reported currently during 1938, amounted to 71,362,000 gallons, a loss of 39 percent from the 1937 total of 117,187,217 gallons. According to trade-journal reports the 1938 average price asked for sulfate of ammonia was $1.43 for 100 pounds, f. o. b. oven or port, an increase of 3 cents compared with the $1.40 price asked in 1937. Prices for benzol, from the same source, remained constant at $0.16 per gallon in tank lots.

## BYPRODUCT COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

Adaptation of the byproduct coke oven to the needs of city-gas manufacture has led a number of gas companies to install batteries of byproduct ovens to supplement or even to replace their coal or water-gas plants. From the point of view of ownership and accounting, these installations are part of the gas utility system, and the Bureau of the Census therefore groups them with the manufactured-gas industry under the title "The Gas and Coke Industries."

From other points of view, however, these installations belong to the byproduct coke industry. The coke produced is superior to gas-house coke. In the practical operation of a byproduct coke plant the fact that the gas may be distributed through city mains has less consequence than the fact that the coke must be marketed for foundry, furnace, or household use. Considered with reference to oven design and the technique of manufacture, and still more with reference to the supply and demand for coke, these ovens should be included with other byproduct coke plants; they are so included in the statistics published by the Bureau of Mines.

These differences in classification are followed by the Bureau of the Census and the Bureau of Mines after consultation with leaders of the gas and coke industries, and the two offices have collaborated in the collection and analysis of the statistics.

The following table presents the salient features of the byproduct coke industry separated with respect to plants owned by city-gas companies and those not so owned.

That the public utility plants have been increasing in number and volume of output is evidenced by the fact that the number rose from 9 in 1918 to 21 in 1929. In the latter year the coke produced from the 21 active plants amounted to 3,232,307 tons, or 6 percent of the total output of byproduct coke. In 1938, with only 18 plants active, the coke product was 3,247,548 tons, a little more than 10 percent of national production.

| Size of plants | 922 |
| Raw fuels | 922 |
| Binders | 922 |

The domestic production of fuel briquets in 1938 totaled 871,260 net tons valued at $5,701,890. This represents a decrease in quantity of 12.5 percent from 1937 and 23 percent from 1936. The decline in 1938 was due principally to the mild winter, but it is believed that unsettled coal prices also may have been partly responsible.

Despite the curtailment in output, interest in fuel briquetting appears to be gaining, as evidenced by the 35 plants in operation in 1938 (8 of them new), the largest number since the beginning of the industry. Three other plants were under construction or being operated experimentally at the end of the year.

The production of packaged fuel in 1938 increased 10 percent, reaching a total of 160,952 tons valued at $1,405,253 compared with 146,037 tons valued at $1,287,320 in 1937. The gain, however, was not so marked as in 1937, when the production was more than double that of 1936. Operators reported that their output in 1938 would have been considerably greater if winter temperatures had been normal.

Reports received by the Bureau of Mines on fuel-briquetting and packaged-fuel operations for 1938 show that these two industries apparently are not competitive, as fuel briquets are designed to stand shipment for a considerable distance whereas packaged fuel is principally for local or nearby consumption. The average fuel-briquetting plant in 1938 produced about 25,000 tons a year and shipped by rail to far destinations, while the average packaged-fuel plant produced only about 3,000 tons, mostly for local consumption.

Statistics on fuel briquets and packaged fuel are presented separately in this report.

[1] Directories of fuel-briquetting and packaged-fuel plants operating in 1938 and names of manufacturers of equipment will be furnished on request by the Coal Economics Division, Bureau of Mines, Washington, D. C.

## FUEL BRIQUETS

The salient statistics of the fuel-briquetting industry from 1934 to 1938 are summarized in the following table.

*Salient statistics of the fuel-briquet industry in the United States, 1934–38*

[Data regarding packaged fuel are given separately at end of this report]

| Year | Production | | | | Imports | Exports [1] | Consumption [2] | Value of production (thousands of dollars) | Plants in operation | Average output per plant (thousands of net tons) | Average value per net ton, f. o. b. plant | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Eastern States | Central States | Pacific Coast States | Total | | | | | | | Eastern States | Central States | Pacific Coast States |
| | Thousands of net tons | | | | | | | | | | | | |
| 1934 | 264 | 388 | 53 | 705 | ------ | (1) | 705 | 4,276 | 27 | 26 | $4.72 | $6.54 | $9.33 |
| 1935 | 310 | 485 | 66 | 861 | 17 | (1) | 878 | 5,476 | 29 | 30 | 4.48 | 7.16 | 9.29 |
| 1936 | 351 | 702 | 72 | 1,125 | 20 | (1) | 1,145 | 7,043 | 32 | 35 | 4.19 | 6.95 | 9.64 |
| 1937 | 271 | 636 | 89 | 996 | 7 | 25 | 978 | 6,394 | 31 | 32 | 4.19 | 7.01 | 8.94 |

[1] Exports not reported separately by Bureau of Foreign and Domestic Commerce prior to 1937.
[2] Production plus imports minus exports.

*Production.*—Production of briquets in 1938 totaled 871,260 net tons, a decrease of 124,670 tons (12.5 percent) from 1937. (See fig. 1.) The greatest relative decrease was in the Pacific Coast States.

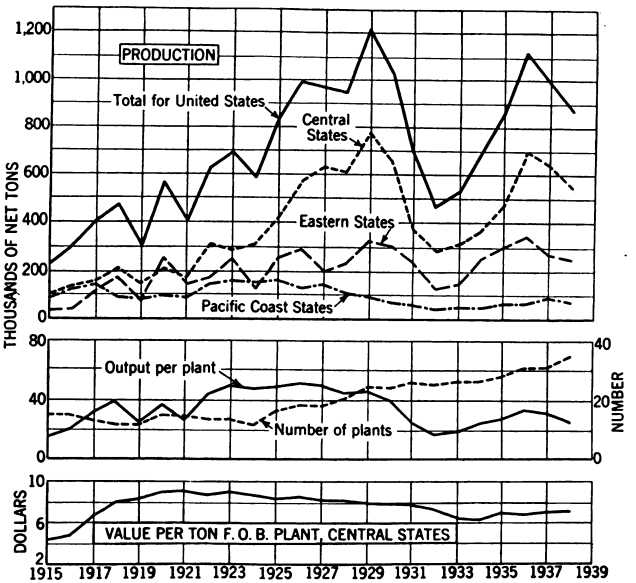

FIGURE 1.—Production of fuel briquets, number of plants in operation, and average value per net ton, f. o. b. plant (Central States), 1915–38.

[1] Includes 10 plants in Wisconsin; 3 each in Minnesota, North Dakota, and Washington; 2 each in California, Michigan, Nebraska, and West Virginia; and 1 each in Arkansas, Illinois, Massachusetts, Missouri, Ohio, Oregon, Pennsylvania, and Wyoming.

The decrease in output of fuel briquets in the Eastern and Central States can be attributed to the mild winter of 1938. Production in the Pacific Coast States, although 17 percent below 1937, was about normal in 1938; production was unusually high in 1937 because of severe freezes in January of that year. The winter of 1938 was so mild that orchard heating—an important market for this fuel on the Pacific coast—was unnecessary.

Wisconsin produces about half the total; West Virginia, Pennsylvania, Oregon, and Missouri follow in order of tonnage produced in 1938. Michigan, Minnesota, Nebraska, Washington, West Virginia, and Wyoming increased their output in 1938.

The following table shows production and value for 1938 in those States for which the figures can be published without revealing operations of individual companies.

*Fuel briquets produced in Wisconsin, North Dakota, Minnesota, and Washington*

| State | 1937 | | | 1938 | | |
|---|---|---|---|---|---|---|
| | Plants | Net tons | Value | Plants | Net tons | Value |
| Minnesota | 3 | 20,905 | $162,136 | 3 | 22,840 | $219,428 |

*Value.*—The total sales value of the briquets manufactured in 1938 was $5,701,890, f. o. b. plant, 11 percent below 1937. The loss in total value is due to the 12.5-percent decrease in production, as the average value per ton rose from $6.42 in 1937 to $6.54 in 1938.

The average for the entire industry is of doubtful significance because of variations in the cost of raw fuel to briquetting plants and in market prices of competing fuels.

The average value per net ton in the Eastern States in 1938 was $4.34, in the Central States $7.18, and in the Pacific Coast States $9.38. These figures do not represent the prices paid by the ultimate consumer.

In the Eastern States the entire output comes from plants in the low-volatile coal fields of southern West Virginia and in the anthracite region of Pennsylvania, where the cost of raw fuel does not involve freight charges. As a result, the f. o. b. value of briquets at these plants is relatively low. In the Central States most of the production comes from plants at coal docks on Lakes Michigan and Superior; the raw fuel for these plants involves a considerable freight charge.

*Technical developments.*—Interest continues in technical research and experimentation. However, no new methods were put into commercial operation in 1938, so far as is known, except at a plant in California where residual carbon from the pyrolysis [2] of natural gas is being used as raw fuel, with the addition of a 14-percent asphaltic pitch binder.

Attention is called to recent papers and discussion on the manufacture of fuel briquets by C. C. Morfit, C. A. Jacobson, and J. L. Knight.[3]

The appeal of packaged products has also penetrated the field of bulk briquets. Two new fuel-briquetting plants have included bagging machinery in their equipment. The product of both plants is the small pillow-shaped briquet, automatically sacked in bags of about 15 pounds and sold locally.

Another briquetting plant, making 3-inch cubes, wrapped several thousand tons (about one-third of its production) in 10-pound packages.

One of the larger briquetting operations, which makes Pennsylvania anthracite briquets, reports that retail dealers are bagging increasing quantities of its product in 17-, 25-, and 50-pound bags.

*Number of plants.*—Thirty-five plants reported commercial production in 1938, the largest number of active fuel-briquetting plants in the history of the industry. Of these, eight are new (one each in California, Michigan, Minnesota, Nebraska, Ohio, and Washington and two in North Dakota).

Three additional plants, situated in Michigan, Pennsylvania, and Texas, were under construction and in experimental operation in 1938.

Sixteen plants were idle in 1938, of which 13 were also idle in 1937. Seven plants went out of business in 1938, but two of these were active part of the year.

*Size of plants.*—The following table classifies the plants according to actual production as well as actual capacities; however, a better indication of the size of plants is gained from their capacity, even though the latter is definitely affected by seasonal variations in production.

The total annual capacity of the 35 plants operating in 1938, as reported by the operators, is 3,111,800 net tons, whereas production was only 871,260 tons. The estimated annual capacity of the eight new plants is about 107,500 tons.

*Classification of briquetting plants in 1938, by size of output and annual capacity*

| Output (net tons) | Plants | Annual capacity (net tons) | Plants |
|---|---|---|---|
| Less than 2,000 | 11 | Less than 5,000 | 3 |
| 2,000 and less than 5,000 | 4 | 5,000 and less than 10,000 | 5 |
| 5,000 and less than 10,000 | 5 | 10,000 and less than 25,000 | 8 |
| 10,000 and less than 25,000 | 5 | 25,000 and less than 100,000 | 12 |
| 25,000 and less than 100,000 | 8 | 100,000 and less than 200,000 | 2 |
| 100,000 and over | 2 | 200,000 and less than 400,000 | 3 |
| | | 400,000 and over | 2 |
| | [1] 35 | | [1] 35 |

[1] 16 plants operated 12 months of the year; 10 plants from 7 to 11 months; and 9 plants less than 5 months

*Raw fuels.*—The total quantity of raw fuel briquetted in 1938 was 836,407 net tons, of which low-volatile bituminous coal formed the greater part. Fourteen plants used 296,133 tons of low-volatile coal exclusively; the total low-volatile utilized amounted to 501,325 net tons—60 percent of the total raw-fuel tonnage.

Nine operators, using 371,139 tons of anthracite and bituminous coal, reported that the raw fuel was washed before it was manufactured into briquets.

*Classification of fuel-briquetting plants by kinds of raw fuel used in 1938*

| Kind of raw fuel used: | *Plants* |
|---|---|
| Anthracite or semianthracite fines exclusively | 3 |
| Mixture of anthracite or semianthracite and bituminous | 5 |
| Bituminous: | |
| Low-volatile | 14 |
| High-volatile | [1] 2 |
| Semicoke (lignite char) | 3 |
| Mixture of petroleum coke with anthracite or bituminous | 3 |
| Residual carbon from pyrolysis of natural gas | 1 |
| Residual carbon from manufacture of oil gas | 2 |
| Petroleum coke | 2 |
| | 35 |

[1] 1 plant using high-volatile coal also reported using residual carbon from manufacture of oil gas.

*Raw fuels used in making briquets in the United States, 1929 and 1936–38*

| | Net tons | | | | Percent of total | | | |
|---|---|---|---|---|---|---|---|---|
| | 1929 | 1936 | 1937 | 1938 | 1929 | 1936 | 1937 | 1938 |
| Anthracite and semianthracite culm and fine sizes | 408,967 | 296,806 | 252,572 | 200,347 | 34.4 | 27.8 | 26.5 | 23.9 |
| Bituminous and subbituminous slack | 711,459 | 645,896 | 569,815 | 505,917 | 59.9 | 60.6 | 59.9 | 60.5 |
| Semicoke, coke, oil-gas residue, or petroleum coke | 67,513 | 123,868 | 129,278 | [1] 130,143 | 5.7 | 11.6 | 13.6 | 15.6 |
| | 1,187,939 | 1,066,570 | 951,665 | 836,407 | 100.0 | 100.0 | 100.0 | 100.0 |

[1] Includes residual carbon from pyrolysis of natural gas at plant in California.

Digitized by Google

Important factors that control the success of a briquetting plant are its location with relation to the source of the raw-fuel supply and to the consuming market for the finished product, freight rates, cost of raw fuel, and prices of competing fuels to the consumer. As borne out in the following table, the plants drawing upon the nearby Lake docks for their raw fuel produced approximately half of the total output in 1938.

*Fuel briquets produced in the United States, 1937–38, with reference to supply of raw fuel*

| Location of plant | Net tons | | Change in 1938 compared with 1937 | |
|---|---|---|---|---|
| | 1937 | 1938 | Net tons | Percent |
| At or near Lake Superior or Lake Michigan coal docks | 507,462 | 422,717 | −84,745 | −16.7 |
| At coal mines | 325,093 | 292,827 | −32,266 | −9.9 |
| At or near petroleum refineries and oil-gas plants | 91,267 | 84,954 | −6,313 | −6.9 |
| At other locations [1] | 72,108 | 70,762 | −1,346 | −1.9 |
| | 995,930 | 871,260 | −124,670 | −12.5 |

[1] 1937—South Chicago, Ill.; Indianapolis, Ind.; Fall River, Mass.; Jackson, Mich.; Minneapolis and St. Paul, Minn.; Kansas City, Mo.; and Omaha, Nebr. 1938—Same as for 1937, except Indianapolis, Ind.

*Binders and recarbonization.*—Asphaltic pitch continues to be the most frequently used binder. Three plants (two using residual carbon from the manufacture of oil gas and one using low-volatile bituminous coal as their raw fuels) reported that no binder was used. The production of the coal plant was small, and all sales were local. One new plant in California, employing residual carbon from the pyrolysis of natural gas for its raw fuel, reported the use of 14 percent asphaltic pitch.

One producer using anthracite as raw fuel reported partial recarbonization to drive off smoke caused by the binder.

*Classification of briquetting plants in 1938, by type and percentage of binder used*

| Type of binder | Plants | Percentage of binder to raw fuel (by weight) | Plants |
|---|---|---|---|
| Asphaltic pitch | 24 | Less than 5 percent | 5 |
| Coal-tar pitch | 1 | 5 and less than 7 percent | 16 |
| Mixed pitches | 2 | 7 and less than 9 percent | 7 |
| Petroleum asphalt | 2 | 9 percent and over | 4 |
| Starch, asphalt, and water | 1 | No binder | 13 |
| Starch | 2 | | |
| No binder | 13 | | 35 |
| | 35 | | |

[1] Includes 2 plants using residual carbon from manufacture of oil gas and 1 plant using bituminous coal as raw fuel.

*Weight and shape.*—The industry has made virtually no change in the prevalent size and shape of fuel briquets. More than 90 percent of the total tonnage in each year since 1930—the first year for which the Bureau of Mines asked the producers to give information on weight, size, and shape—has consisted of briquets weighing less than 5 ounces.

Digitized by Google

*Prevailing weight of briquets produced in 1938*

| Weight (ounces) | Plants | Production | | Weight (ounces) | Plants | Production | |
|---|---|---|---|---|---|---|---|
| | | Net tons | Percent of total | | | Net tons | Percent of total |
| Less than 2 | 5 | 57,107 | 6.5 | 5 and under 6 | 1 | 17,488 | 2.0 |
| 2 and under 3 | 14 | 479,314 | 55.0 | 6 and under 10 | 1 | | |
| 3 and under 4 | 5 | 245,426 | 28.2 | 10 and under 16 | | | |
| 4 and under 5 | 5 | 71,925 | 8.3 | 16 and under 25 | 6 | | |
| | | | | 42 and over | 1 | | |
| | | | | | [1] 35 | 871,260 | 100.0 |

[1] 3 plants made briquets of more than 1 size, hence the sum of the items exceeds the number of active plants. Of the 8 new plants, 5 made briquets between 2 and 5 ounces and 3 between 16 and 42 ounces.

The pillow-shaped briquet continues to be the most popular. Of the 35 plants active in 1938, 25 made pillow-shaped briquets, 6 cubes, and 2 cylindrical. One plant reported making three different shapes—pillow, cube, and cylindrical; another plant made pillow and cylindrical shapes.

*Principal expenses and value added by manufacture.*—Data on the cost of manufacturing fuel briquets and packaged fuel are not collected by the Bureau of Mines.

Information on the principal items of expense (salaries; wages; cost of materials, fuel, electric energy, and contract work; value of product; and value added by manufacture) is collected and published by the Bureau of the Census in alternate years.

The Census classification of the fuel-briquetting industry includes only those establishments with an output valued at $5,000 or more in which briquets are the chief products made. The Bureau of the Census therefore excludes briquets produced at petroleum refineries or at city gas works, but the returns are representative of independent briquetting plants.

Data for 1937 are now available and may be obtained upon application to the Bureau of the Census, United States Department of Commerce, Washington, D. C.

*Distribution.*—In 1938 briquets were shipped to 35 States, the District of Columbia, Alaska, and Canada. Minnesota and Wisconsin consumed about 45 percent of the total, the same proportion as in 1937. States reporting the largest output in 1938 shipped their briquets as follows: From Wisconsin to 9 States; from West Virginia to 18 States and Canada; and from Pennsylvania to 15 States, the District of Columbia, and Canada. The States consuming all or most of their production locally were: Massachusetts, Illinois, Michigan, Minnesota, Nebraska, North Dakota, Ohio, California, Oregon, and Washington.

Particularly noteworthy was the single shipment on January 11, 1938, of about 5,000 tons of briquets in a solid train of 100 cars from Glen Rogers, W. Va., to Toledo, Ohio, for ultimate distribution to customers in Michigan cities.[4]

[1] As reported by the operators to the Bureau of Mines; official figures on imports and exports are given in following tables.

In the questionnaire for 1938 the Bureau of Mines for the first time requested information on the tonnage shipped by rail, truck, and waterway. The results, given in the following table, indicate that 80 percent of the tonnage moved by rail and the rest by truck (including local deliveries).

*Fuel-briquet shipments by rail and truck in 1938, in net tons*

| | Rail | Truck [1] | Total |
|---|---|---|---|
| Eastern States | 246,673 | 3,449 | 250,122 |
| Central States | 423,246 | 127,215 | 550,461 |
| Pacific Coast States | [2] 23,952 | 42,864 | 66,816 |
| Total United States | 693,871 | 173,528 | 867,399 |

[1] Includes local deliveries.
[2] Includes 28 tons subsequently shipped from Seattle, Wash., by water to Alaska.

*Imports and exports.*[5]—In 1938 imports of fuel briquets rose to 13,814 net tons all from Belgium and the Netherlands, and all entering Massachusetts, Maine, and New Hampshire. Exports dropped to 16,692 tons, valued at $123,309, of which all but 2 tons went to Canada.

*Briquets (coal and coke) and other composition coals for fuels imported for consumption in the United States, 1934–38*

| Year | Net tons | Value | Year | Net tons | Value |
|---|---|---|---|---|---|
| 1934 | (1) | (1) | 1937 | 6,674 | $28,549 |

## PACKAGED FUEL

The production of packaged fuel continues to expand and apparently has definitely passed the pioneering stage. In 1938, 76 plants produced 160,952 tons valued at $1,405,253—three times as many active plants as in 1935 and nearly three times the value reported in 1936. The increase over 1937 was 14,915 tons (10 percent).

Of the 76 plants, 67 are in the Central States; Michigan, Ohio, Wisconsin, and Minnesota are the most important producing States.

Packaged fuel is manufactured principally for local or nearby consumption, but five operators, whose plants are located at docks on the Great Lakes, reported shipments by rail in 1938 of about 5,000 tons to points within a radius of 500 miles.

The National Association of Packaged Fuel Manufacturers held its second meeting in Chicago on September 15, 1938. A discussion of this meeting in Packaged Fuel News[6] stated that the technical problems confronting the industry have been largely overcome and that further expansion is expected through cooperation of its members in aggressive merchandising methods.

Numerous inquiries from foreign countries indicate interest in the manufacture of packaged fuel abroad. According to an established packaged-fuel machine manufacturer, however, difficulties in arranging for overseas shipment of machinery and other necessary supplies have interfered with the foreign sales of such equipment.

*Production and value.*—The following table summarizes the production and value received at the plant for the packaged fuel manufactured in the United States, 1937–38.

*Packaged fuel produced in the United States, 1937–38, by States*

[The plants and production reported in this table are not included in the preceding fuel-briquet tables]

| State | 1937 | | | 1938 | | |

December and July, respectively, continue to be the high and low months of production in the packaged-fuel industry. In month to month comparisons, however, it should be remembered that a number of new plants started operating in the latter part of both 1937 and 1938.

*Monthly production of packaged fuel in the United States in 1937–38, in net tons*

| Month | 1937 | 1938 | Month | 1937 | 1938 |
|---|---|---|---|---|---|
| January | 15,344 | 22,095 | August | 2,131 | 2,252 |
| February | 15,076 | 17,124 | September | 10,377 | 13,198 |
| March | 16,439 | 15,710 | October | 21,164 | 19,671 |
| April | 15,286 | 13,673 | November | 21,976 | 23,271 |

| Michigan | 8.62 | 8.40 | Pacific Coast States | (1) | (1) |
| Minnesota | 11.44 | 11.38 | United States average | 8.82 | 8.73 |

[1] Bureau of Mines not at liberty to publish figures.

*Processes.*—Of the 76 operations in 1938, 72 used the Eberling process[7] described in previous reports of this series. The other four operations are outlined briefly in the following paragraphs.

The Johnson Coal Cubing Co.,[8] of Detroit, Mich., uses a process and equipment of its own design, producing a cube-shaped briquet wrapped in heavy paper, eight to the package. This company, which is the largest of the packaged-fuel operations, started production in 1932.

A new plant in Grand Rapids, Mich., reported the first installation of a machine that produces bricks (6½ by 3½ by 4 inches) which are hand-packed three to a paper bag and weigh 10 to 11 pounds.

A new plant in Minneapolis, Minn., which started operations late in 1938 with still another type of machine, uses asphalt binder instead of the cornstarch usually employed in the manufacture of packaged fuel. Eight 3-inch cubes to the package are automatically wrapped in heavy paper by a specially designed wrapping machine with a capacity of 40 packages per minute or 12 tons per hour.

[7] Packaged Fuel by the Eberling Process: 1938 catalog issued by C. M. Eberling, 6002 Ellen Avenue, Cleveland, Ohio.

[8] The Black Diamond, vol. 102, No. 7, Apr. 8, 1939, p. 23.

Digitized by Google

A new plant operated by eight local coal yards in Fort Wayne, Ind., has installed a machine of the tamp type that produces 4-inch cubes, which are paper-wrapped, four to the package.

*Number of plants.*—Of the 76 active plants in 1938, 16 reported operations for the first time. All but one of the new plants are in the Central States region. Eight plants were idle in 1938; several of these found it more profitable to buy the packaged fuel from other manufacturers for resale. One company went out of business in 1938.

*Size of plants.*—Sixty-one of the 76 packaged-fuel plants active in 1938 produced less than 3,000 tons each during the year; 16 of these were new (of which five operated 12 months and 11 but a few months in 1938). Reports submitted on individual capacities indicate that the 76 plants were equipped to produce (if necessary to supply the demand) an annual total of about 500,000 tons.

*Classification of packaged-fuel plants in 1938, by size of output and annual capacity*

| Output (net tons) | Plants | Annual capacity (net tons) | Plants |
|---|---|---|---|
| Less than 500 | 17 | 2,000 and less than 5,000 | 38 |
| 500 and less than 1,000 | 14 | 5,000 and less than 10,000 | 26 |
| 1,000 and less than 3,000 | 30 | 10,000 and less than 15,000 | 6 |
| 3,000 and less than 5,000 | 10 | 15,000 and less than 25,000 | 2 |
| 5,000 and less than 10,000 | 3 | 30,000 and less than 40,000 | 3 |
| 10,000 and less than 25,000 | 1 | 40,000 and less than 60,000 | |
| 25,000 and over | 1 | 60,000 and over | 1 |
| | [1] 76 | | [1] 76 |

[1] 12 plants operated 12 months of the year; 49 plants, 6 to 11 months; and 15 plants, 1 to 5 months (11 of these new in 1938).

*Raw fuels.*—The tendency in 1937 toward the use of shipped-in slack from the mines and Lake docks as raw fuel in the manufacture of packaged fuel became more prevalent in 1938, when 46 out of 76 plants used shipped-in slack exclusively; 15 plants used both shipped-in slack and yard screenings and 12 plants yard screenings exclusively. Four operators did not reply to this question.

The principal raw fuel is bituminous low-volatile slack, which was used exclusively by 67 operators; 1 operator used bituminous high-volatile slack, 3 petroleum coke, 1 semianthracite, and several operators used mixtures of these various fuels.

*Binders.*—Cornstarches remain the principal binders used. Two operators reported using cement, one asphaltic pitch, and one glue.

# PEAT

By F. M. Shore

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 923 | Uses | 925 |
| Reserves | 923 | Imports | 925 |
| Production | 923 | World production | 926 |

The commercial production of peat and peat humus in the United States declined materially in 1938, according to reports courteously furnished by producers to the Bureau of Mines. The total production amounted to 45,933 short tons valued at producing plants at $286,127, a reduction of 10 percent in tonnage and 6 percent in value from 1937. Imports of peat moss also declined substantially in 1938 to 69,509 short tons valued at $1,092,942 as against 86,871 tons valued at $1,219,127 in 1937, a loss of 20 percent in quantity and 10 percent in value. The total quantity of peat and peat humus available for domestic consumption in 1938 (domestic production plus imports) was 115,442 short tons, a reduction of 16 percent from 1937. The downward trend in peat production in 1938 was in line with, but less than, the drop in industrial production generally. It will be noted, however, that the average value per ton of peat in 1938 was larger than in 1937, as well as that of peat-moss imports.

*Reserves.*—The total quantity of peat in the United States, exclusive of Alaska, calculated as air-dried peat, has been estimated at 13,827,000,000 short tons.[1] The area of the lands that contain peat deposits probably exceeds 100,000,000 acres. The bulk of the peat reserves is in the States of the Upper Lakes region—Minnesota, Wisconsin, and Michigan together having about 75 percent of the total. Substantial deposits of peat occur in other States bordering the Great Lakes and the Atlantic and Pacific coasts. About half the States contain some peat, but not all of the deposits can be developed economically.

The texture and quality of peat deposits and the value of the peat for specific uses may vary greatly because of different plant origins, conditions under which the deposits were formed, and stages of development. The various factors individual to each peat deposit, including its potential markets, character, and circumstances of deposition, must be studied carefully before its possibilities for profitable development can be determined.

*Production.*—Figure 1 shows the annual production of peat in the United States since the industry attained commercial importance.

The quantity and value of the domestic output of peat in recent years are given in the following table.

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

*Peat produced in the United States, 1926 and 1934–38* [1]

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1926 | 61,936 | $364,413 | 1936 | 46,126 | $266,883 |
| 1934 | 40,544 | 214,185 | 1937 | 51,223 | 305,156 |
| 1935 | 37,060 | 199,377 | 1938 | 45,933 | 286,127 |

[1] No canvass 1927–33, inclusive.

Output of peat in 1938 was reported by 39 producers operating plants in 14 States. The same States produced peat in 1938 as in 1937, but there were three less producers. The 1938 production totaled 45,933 short tons valued at $286,127. In 1938, as in 1937, New York and New Jersey were the largest producing States. Other States reporting commercial production of peat, in order of output,

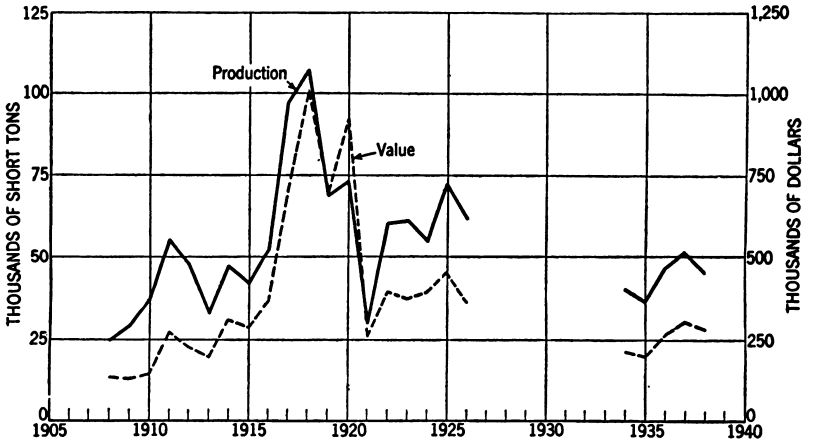

FIGURE 1.—Quantity and value of peat production, 1908–38. No data are available for the period 1927–33.

were Michigan, California, Florida, Ohio, Colorado, Minnesota, Iowa, Washington, Pennsylvania, New Hampshire, Maine, and Massachusetts. The production from some of these States was of little economic consequence, and the wide distribution of producing operations is more significant of the scope and potential value of peat resources and possible future markets than it is of present utilization. Approximately 58 percent of the production in 1938 was peat humus, about 32 percent reed and sedge peat, and the remainder moss and various other kinds of peat. Twelve States produced peat humus, five reed or sedge peat, and seven moss peat. Two plants reported the production of kiln-dried peat, 7 of cultivated peat, 27 of shredded peat, and 16 of raw peat.

The Bureau of Mines attempts to report only the commercial production of peat; however, this tonnage does not represent the total utilization of domestic peat in the United States. Some municipalities operate peat plants for their own needs, such as to improve the soils of lawns and parks, and many owners of land containing peat or muck soils use them for growing vegetables or other crops.

Digitized by Google

Data showing the area of peat and muck soils under cultivation are not available, but the total amounts to many thousands of acres. It should be noted that such use of peat is an important factor in economic utilization of the national peat resources.

*Uses.*—Peat can be used for many purposes, but its use in this country is confined largely to improvement of soils, directly as a soil conditioner or an ingredient of fertilizers or indirectly as a compost with animal or vegetable refuse. The producers of peat were asked to report, in connection with their 1938 production, the quantity of peat sold for use in mixed fertilizers, but the reports were too incomplete to warrant publication. Peat is employed to some extent as a packing material for the shipment of plants, vegetables, fruits, or fragile articles and as an insulating material. Its chief use is for improving soils for growing vegetables, fruits, flowers, trees, shrubbery, and grass; in gardens, nurseries, and greenhouses; and on lawns, golf courses, and parks. The reports of peat and peat-humus sales in 1938 indicated that 76 percent was sold for soil improvement. Other uses reported were stable and poultry litter and packing material. In many European countries peat is used widely as a domestic fuel, and in some of them substantial quantities are used for industrial fuel. In the United States peat cannot compete under present conditions with high-grade fuels that are so widely available. No sales of domestic peat for fuel have been reported in recent years.

*Imports.*[2]—Imports of peat moss in 1938 decreased in total quantity and value from the 1937 record, although the average value per ton was greater than in 1937. The tonnage was 20 percent and the total value of imports 10 percent below 1937 figures. The chief sources of imports of peat moss in 1938 were, in order of tonnage, Germany, Sweden, the Netherlands, and Canada. Imports from Canada showed a substantial gain, continuing the upward trend that began in 1934.

Imports of peat moss into continental United States were received through 25 customs districts, indicating the wide geographical distribution of its use. Most of the imports (approximately 63 per cent) were received at Atlantic coast ports, although some 10,000 tons entered through Gulf ports and 14,000 tons through Pacific ports.

The average value per ton of peat-moss imports increased again in 1938, continuing a trend that has prevailed for several recent years. It was $10.74 in 1933, $12.40 in 1934, $12.42 in 1935, $12.73 in 1936, $14.03 in 1937, and $15.72 in 1938. The average value reported varies considerably with the country of origin. For example, imports from Canada in 1938 were $22.85 per ton, Latvia $21.30, Sweden $18.66, Germany $14.45, and the Netherlands $9.83.

*Peat moss imported for consumption in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 44,132 | $547,353 | 1937 | 86,871 | $1,219,127 |
| 1935 | 54,547 | 677,513 | 1938 | 69,509 | 1,092,942 |
| 1936 | 75,066 | 955,807 | | | |

*World production.*—It is difficult to obtain comprehensive and current data regarding world production of peat. Apparently some peat-producing countries do not compile data showing the quantities produced, and the units of quantity used by countries that do report production are not uniform. The data in the following table, although not complete, will prove of interest to those concerned with the production and use of peat, as they represent the latest information now available.

The relative proportion contributed by the United States to world oil production fell from 62.7 percent in 1937 to 61.3 percent in 1938. The 1938 decline of 66 million barrels in United States crude oil production, owing to depressed domestic demand and efforts to reduce crude and refined stocks to more economic levels, was offset by an increase of only 2 million barrels for all other world producers combined. Consequently, total world production fell from 2,042 million barrels in 1937 to 1,978 million in 1938, a decrease of 64 million. Increases of 7 million barrels in Russian output, 4 million in Canada, and smaller gains in other producing countries were largely balanced by the decline of 12 million barrels in Mexican production that resulted from expropriation of oil properties by the Government and the decline of 4 million barrels in Rumanian output.

The total exports of crude and refined products from continental United States rose from 173 million barrels in 1937 to 194 million in 1938, while total imports fell from 57 to 54 million. This substantial gain in net exports was due in part to the accumulation of strategic stocks abroad.

The combined domestic and export demand for all oils in 1938 decreased about 14 million barrels from the 1937 all-time peak of 1,342 million. As exports of all oils increased 21 million barrels, domestic demand was reduced by 35 million barrels. A decline of 9 percent (30 million barrels) in the total demand for residual fuel oils was the major feature in 1938.

Although the drop in the total volume of the oil industry's business was only a little over 1 percent, slight progress was made in reducing

[1] Data for 1938 are preliminary; detailed statistics with final revisions will be released later.

Digitized by Google

the excessive inventories accumulated in 1937, and prices of refined products trended steadily downward during the year, followed by a sharp break in crude prices in October. Many small refineries were closed when operations became unprofitable, and the net profits of many of the larger integrated companies were sharply reduced.

The following table shows the trend in the demand for all oils since 1929.

*Total demand for all oils, 1929–38*

[Millions of barrels]

| Year | Domestic demand | Exports | Total demand | Year | Domestic demand | Exports | Total demand |
|---|---|---|---|---|---|---|---|
| 1929 | 940.1 | 163.1 | 1,103.2 | 1934 | 920.2 | 114.5 | 1,034.7 |
| 1930 | 926.4 | 156.5 | 1,082.9 | 1935 | 983.7 | 129.0 | 1,112.7 |
| 1931 | 903.2 | 124.4 | 1,027.6 | 1936 | 1,092.7 | 132.0 | 1,224.7 |
| 1932 | 835.5 | 103.3 | 938.8 | 1937 | 1,169.7 | 172.8 | 1,342.5 |
| 1933 | 868.5 | 106.7 | 975.2 | 1938 [1] | 1,134.2 | 193.9 | 1,328.1 |

[1] Subject to revision.

The sharp, unexpected drop in the upward trend of demand in the last quarter of 1937 resulted in a rapid increase in total stocks that was augmented in the first quarter of 1938, before the domestic industry could adjust itself to the change in market demand. Subsequent efforts to reduce inventories to a more normal level represent a dominant factor in operations during the remainder of the year.

Stocks of all oils were reduced by 10 million barrels in 1938, representing a decline of 29 million barrels in crude stocks and an increase of 19 million barrels in refined stocks. The decrease in crude stocks was due to active proration control by various State conservation agencies in an effort to correct the excessive inventories of all oils. This effort was largely offset by refinery operations on a larger scale than was necessary to meet demand. The position of total stocks east of California was improved by a total reduction of 41 million barrels, of which 39 million represented crude oil and only 2 million refined oils. Total stocks of California oils increased by 31 million barrels, of which 10 million represented crude oil and 21 million, refined products.

[8] American Petroleum Institute.
[9] Dealer's net. Comparable tank-wagon prices are no longer available.

There was virtually no change in the demand for foreign crude petroleum, as runs to stills remained the same in spite of a decline in imports.

The total demand for domestic crude in 1938 fell 20 million barrels from that of the previous year. An increase of 10 million barrels in exports indicated a decline of 30 million barrels in the internal demand for domestic crude. This amount represented a decrease in 1938 of about 18 million barrels in runs to stills and of 12 million in crude used for fuel and losses. The recession in the latter item may have been due to substantial reductions in the price of residual fuel oil, while the price of crude oils remained unchanged until late in the year.

With a decline of 66 million barrels in the total production of crude petroleum in the United States, the relative position of the States producing over 10 million barrels changed extensively in 1938. Texas, California, and Oklahoma continued to rank as the three leading producers, but their percentage of the total fell from 76 percent in 1937 to 74 percent in 1938. Production in Texas decreased 35 million and in Oklahoma 54 million barrels, and production in California increased 11 million. The increase of 16 million barrels in Illinois production raised the rank of the State from eleventh in 1937 to seventh in 1938.

The more important trends of the year are indicated by a brief analysis of major operations by quarters.

During the first quarter of 1938 total demand for all oils was about 1 percent greater than for the same period in 1937. Actually, this represented a figure far below expectations, with the result that production and refinery operations exceeded requirements, and about 5 million barrels were added to crude stocks and 18 million to refined stocks. By the end of March stocks of finished and unfinished gasoline had reached an all-time record of over 92 million barrels. The demand for residual fuel oil was 12 percent below that in the first quarter of

Digitized by Google

1937, and the demand for gas and distillate fuels was virtually unchanged. The situation was improved somewhat by a gain over the same period in 1937 of 7 million barrels in crude exports.

In the second quarter of 1938 compared to the same period of 1937 the demand for all oils declined by 8 million barrels and stocks of all oils were reduced 15 million barrels, mostly crude. The domestic demand for motor fuel dropped 1 million barrels but was offset by a gain of 3 million in exports. The total demand for residual fuel oils declined 15 percent from 1937.

In the third quarter the demand for all oils was 16 million barrels less than for the same period in 1937. Stocks of crude oil were reduced by over 10 million barrels, while stocks of other products increased about 3 million. The total demand for motor fuel was about 3 million barrels less than in 1937, unfavorable weather conditions in July and September being an important factor. The demand for residual fuel oils was still 12 percent below that of the previous year.

In the fourth quarter of 1938 the demand for all oils was 7 million barrels greater than for the same period in 1937. Although part of this increase may be due to the fact that a sharp downward trend was evident in that period in 1937, it also is evidence of the beginning of a substantial improvement in the trend of demand in 1938. Total stocks of all oils decreased 21 million barrels during the quarter, of which 9 million represented crude and 12 million, other oils. Total motor fuel demand was 8 million barrels greater than in 1937, an increase of 5 million in domestic demand, partly due to favorable weather conditions, and of 3 million in exports. As compared to 1937, increased demand and restricted refinery operations resulted in a substantial improvement in the position of gasoline stocks. The demand for residual fuel oils rose 3 percent, and there was a substantial decrease in residual stocks. The improved trend of demand in this quarter continued in the early part of 1939.

In reviewing the demand for particular products in 1938, the outstanding features were a moderate increase in total motor-fuel demand, a sharp reduction in the demand for residual fuel oils, a stationary market for gas and distillate fuel oils and kerosene, and a decline in the demand for lubricants.

The total demand for motor fuel attained a new record of 572 million barrels in 1938, a gain of 14 million from 1937. Larger exports accounted for 12 million barrels of the increase, while domestic demand was only 2 million greater. The gain of about 14 million barrels of finished and unfinished gasoline stocks in 1937 was only partly offset by a decline of 5 million in 1938. High inventories combined with the modest increase in demand created an unstable price situation throughout the year, resulting in unprofitable refinery operations in many districts. The yield of gasoline from crude rose from 43.9 percent in 1937 to 44.3 percent in 1938, due in part to the adoption of improved refinery methods of recovery and in part to the combination of larger runs than necessary, with a weak market for residual fuel oils.

Digitized by Google

The total demand for residual fuel oils in 1938 decreased over 30 million barrels from 1937. As exports increased by almost 3 million barrels, this loss was entirely in the domestic market. Stocks of residual fuel oils increased by 16 million barrels during 1938, a gain of 17 million barrels in California and a decline of 1 million in the districts east of California. The large increase in California stocks was due to excess production of crude oil that was run to stills, with a corresponding production of refined products above market demand. In the area east of California very little progress was made in liquidating the large excess of residual stocks accumulated in 1937. However, improved industrial demand, combined with lower prices for residual fuel in the last quarter of 1938 and the first quarter of 1939, promised to reduce these excessive inventories in the central and eastern districts.

The total demand for gas oil and distillate fuel oils in 1938 was virtually the same as in 1937, both for domestic demand and export. The year ended with an increase of 5 million barrels in inventories. A considerable part of this increase represented the return of California stocks to a more normal position. Comparatively mild weather in the first and fourth quarters of 1938 reduced the expected increase in the demand for heating oils, while transportation and industrial requirements were generally reduced by less favorable industrial conditions.

The total demand for kerosene in 1938 was practically the same as in 1937, with a gain of about 1 million barrels in domestic demand and a corresponding decrease in exports.

The total demand for lubricants was 11 percent less than in 1937. Domestic demand declined by 2 million barrels in 1938, while exports also decreased.

The long-term trends in supply and demand are shown in figure 1.

## RESERVES

The proved oil reserves of the United States were estimated at 17,348 million barrels as of January 1, 1939, in a report prepared by the Committee on Petroleum Reserves of the American Petroleum Institute. This estimate may be subject to later revision. It presents only the amount of crude oil that may be extracted by present known methods from fields completely developed or drilled or sufficiently explored to permit reasonably accurate calculations. The following table shows the previous estimates of reserves made by this committee, the figures for January 1, 1935, 1937, and 1938, being final and those for 1939 preliminary, subject to later revision.

*Estimates of proved oil reserves in the United States, on January 1, 1935 and 1937–39, by States* [1]

[Millions of barrels]

## LEGISLATION AND PRORATION

In 1938, as in 1936 and 1937, State and Federal regulation, including taxes, on petroleum maintained the "status quo." Most of the State legislation was routine in character, and no additions were made to the ranks of the prorating States or to the Interstate Oil Compact. The principal functions of the Federal Government in regulation of public lands continued to be those relating to the Connally Law. Several taxes of the Federal Government were not renewed.

The Bureau of Mines forecasts of demand by States were issued monthly throughout the year. As indicated in the table, actual production for the United States averaged about 60,000 barrels less than

Digitized by Google

the estimates of demand. Crude-oil stocks were drawn on about 85,000 barrels daily, hence the actual demand for crude oil ran about 25,000 barrels daily, or less than 1 percent above the Bureau's estimates. The Bureau's record in estimating gasoline demand in 1938 was even better, the margin of error being less than one-half of 1 percent.

## EMPLOYMENT AND LABOR PRODUCTIVITY

The Bureau of Mines canvass of workers in the oil fields indicated an average employment of 121,371 for 1937, or 7 percent above the revised figure of 113,839 for 1936. The factors responsible for this

Digitized by Google

gain were essentially the same as those underlying the material gain in number of workers in 1936, namely, higher prices and better profits, increased drilling, more wells connected to lines, and higher production. The totals above include the average number of part-time workers, totaling 12,903 in 1936 and 12,321 in 1937. Probably many of the new full-time employees in 1937 were recruited from the ranks of the part-time workers. Scattered returns for 1938 indicate a decline in employment, and the total number of workers for that year may not exceed the total of about 114,000 for 1936.

More oil-field workers were employed in 1937 than in 1936 in the majority of the States, only Colorado, Indiana, Montana, Ohio, and West Virginia showing declines. The largest relative gain was in Illinois, where recently discovered fields gave employment to about 500 new wage earners.

[1] Figures for 1938 not yet available.
[2] Revised figures.
[3] Missouri, Tennessee, and Utah.

The average number of hours per week increased from 39.5 to 40.5 for the full-time workers, but the total hours of the part-time workers declined from an average of 835 in 1936 to 811 in 1937. Total man-hours increased from 217,988,000 in 1936 to 239,834,000 in 1937, a gain of 10 percent. Dividing total production by total man-hours gives labor-productivity averages of 5.04 barrels per man-hour in 1936 and 5.33 barrels in 1937. The gain is indicative of the extent to which technologic advances are outstripping increasing physical difficulties.

## CRUDE PETROLEUM

### SUPPLY AND DEMAND

Although production declined 5 percent in 1938 from 1937 the total demand for crude oil decreased less than 20,000,000 barrels, or about 1.5 percent. As imports of crude oil were about the same in the 2

Digitized by Google

years, the statistical explanation lies in the trend of crude-oil stocks, which in 1938 were reduced about 29,000,000 barrels compared with a gain of about 18,000,000 barrels in 1937. Actually, the decline in real demand for crude oil in 1938 was less than is indicated above (1.5 percent), as the increase in refined inventories in 1938, while substantial, was less than in 1937.

The demand for heavy crude oil as fuel without refining declined materially, following the general stagnation of the fuel-oil market, but this loss of business was more than offset by a 10,000,000-barrel increase in exports.

[3] Includes California heavy crude.
[4] Includes shipments to Alaska, Hawaii, and Puerto Rico.
[5] East of California.

## PRODUCTION

As shown in figure 2, the general trend of crude-oil production in 1938 was downward, as the fact gradually dawned that demand would be less than in 1937 and as proration restrictions were accordingly tightened. More specifically, the fluctuations in the trend correlate closely with the Saturday and Sunday shut-downs in Texas. The Sunday shut-downs, instituted January 23, 1938, were instrumental principally in preventing production from rising much above the 3,400,000-barrel mark; but the Saturday shut-downs, first added on May 14 and in effect over most of the remainder of the year, reduced production to below 3,300,000 barrels. Most of the other States with regulatory bodies assisted in the curtailment program, the decline in Oklahoma more than offsetting the gain in Illinois.

Texas continued to produce more than California and Oklahoma combined, but its proportion of the national total declined from 39.9 percent in 1937 to 39.2 in 1938. California's share increased materially, but Oklahoma's percentage in 1938 (14.4) was the lowest since 1906, when the State was coming into prominence. The most notable

Digitized by Google

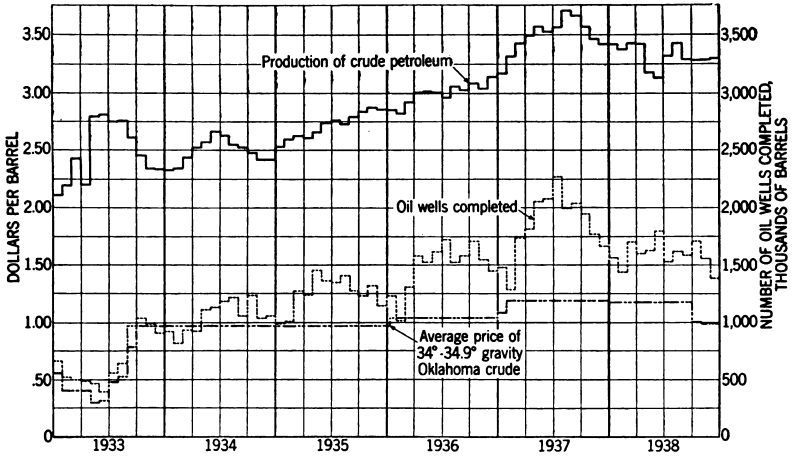

FIGURE 2.—Daily average production of crude petroleum, total number of oil wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum, 1933–38, by months.

increase of any State in 1938 was made by Illinois, whose percentage rose from 0.6 in 1937 to 2.0 in 1938.

The relative rank of the producing States is shown graphically in figure 3.

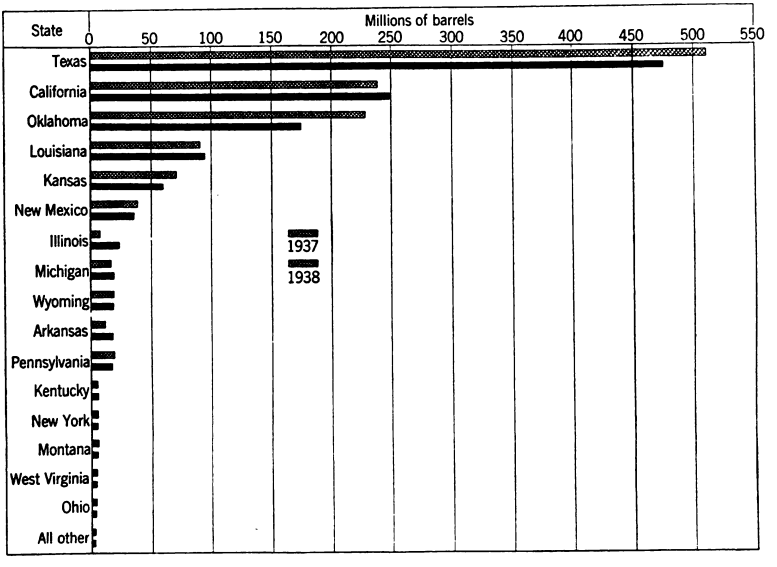

FIGURE 3.—Production of crude petroleum, 1937–38, by States.

Although output in the majority of the producing districts increased in 1938, these gains were far outweighed by the decline in the Mid-Continent. The district with the most notable series of gains is the Gulf Coast, which has increased steadily in output since 1932.

The upward trend in the production of Pennsylvania Grade oil was interrupted in 1938, when the output in all four of the States yielding this type of oil declined. The total production in 1938 was 27,316,000 barrels compared with 29,862,000 in 1937. The decline, most of which was in the Bradford field, was caused by the price reductions of 1938, aggregating 27 percent, or 70 cents per barrel.

*Arkansas.*—Considering the steady decline in production in Arkansas from 1925 to 1937, the gain from 11,764,000 barrels produced in 1937 to just over 18,000,000 barrels in 1938 was sensational. This advance was due primarily to the active development of the Schuler field, although Rodessa also helped out. About 200 oil wells were completed in 1938, or approximately double the 1937 total.

The new discoveries of 1938 were limited almost entirely to Smackover lime pools in Columbia County. Of these the Magnolia field appeared most important.

[1] Figures by districts for 1938 not yet available.

*California.*—Production increased in California in 1938 for the fifth successive year, although the gain was not as large as that of 1937 over 1936. Although exports held up well, the total being slightly higher than in 1937, the domestic demand for all oils was materially lower. The increase in production, therefore, largely represented the degree to which curtailment efforts were outweighed by the superior forces of potential capacity. The voluntary proration program was heroically projected at various times, but the goal of 600,000 barrels of daily production was not in sight until very late in the year.

Measured in terms of number of wells, drilling declined materially in 1938 from 1937. However, from the standpoint of total footage there was little if any decrease, and in initial production there was a large gain. Thus the average initial per well per day for the oil wells completed in 1938 was about 930 barrels compared with about 540 barrels in 1937.

[1] Central Committee of California Oil Producers.
[2] American Petroleum Institute.
[3] Included under "Other San Joaquin Valley."

Most of the fields declined in output in 1938, and only Wilmington, Santa Maria, Torrance, and Rosecrans increased appreciably. The Wilmington field became the leading field of the State by virtue of a gain from 14,186,000 barrels produced in 1937 to 34,168,000 barrels in 1938.

Exploration was extensive and generally successful in California in 1938, and a sizable net addition was made to reserves. Most of the new discoveries were in Kern County; the average depth of the new fields was about 8,000 feet. In point of reserves probably the Southeast Coalinga field was the most important discovery in California in 1937, but in general interest the Wasco discovery, Kern County, ranked first, because the discovery well set a new depth record of 15,004 feet, although the production was obtained from a zone at about 13,000 feet. Drilling in the Canal, Greeley, Montebello, Rio Bravo, Torrance, and Wilmington fields uncovered substantial new reserves, chiefly in new deep sands.

*Colorado.*—The downward turn in production in Colorado, which began in 1937, was accentuated in 1938 when only about 1,400,000 barrels were produced compared with 1,605,000 barrels in 1937. Seven oil wells were brought in in 1938 compared with only two in 1937, yet the total initial increased but slightly.

The Nelson Creek discovery of late 1937 was followed up with some success in 1938. The oil-producing areas within the Hiawatha gas field of Moffat County were enlarged during the year.

*Illinois.*—Production in Illinois was trebled in 1938 over 1937, the output rising from 7,499,000 barrels to about 24,000,000 barrels. The 1938 production did not constitute a new record, several years around 1910 having larger totals. However, it is virtually a certainty that 1939 will bring a new peak. Production in 1938 rose steadily throughout the year, starting at about 35,000 barrels daily and reaching about 135,000 barrels by December 31. Drilling increased rapidly up to October, after which it tapered off with the advent of cold weather. At present the State ranks second only to Texas in completions.

Although the fields of Clay and Richland Counties in east central Illinois, the center of development in 1937, probably led in production in 1938, these fields declined rapidly as the center of interest shifted westward to the new discoveries in the Centralia district. These were the Centralia townsite pool, which had a rapid rise and decline in the middle of the year; Salem or Lake Centralia, the production of which rose to 50,000 daily by the end of the year; and Louden, in Fayette County, which was more conservatively developed than the others. In all fields 1,806 oil wells were completed compared with 272 in 1937 and 27 in 1936.

Another discovery of note was the finding of oil in the Devonian of the old Sandoval field. The fields of Clay and Richland Counties produce from the McClosky lime; but in the Centralia district the Benoist sand, several hundred feet above, was of primary importance until more and more operators began to explore the McClosky late in the year.

*Indiana.*—Although the number of oil wells completed in Indiana in 1938 declined slightly, the total initial trebled and the production rose from 844,000 barrels in 1937 to 969,000 barrels in 1938. The interest in Illinois developments spread to Indiana, and the resulting discoveries appeared more important than in many years.

*Kansas.*—The loss of markets and decline in price of crude dampened the enthusiasm of drillers in Kansas in 1938, and the number of oil wells completed—1,108—was about 40 percent lower than in 1937 and even below the level of 1936. However, wildcatters were unusually successful, and nearly 60 new pools were opened. These were scattered over more than a score of counties, Russell, Barton, and Stafford being prominent. Production crept farther west, Finney, Ford, and Graham Counties being added to the producing column in

Digitized by Google

1938. Other interesting field developments were the increase in water-flood projects in the old southeastern fields and the prospecting in that part of the Forest City Basin that extends into northeast Kansas.

The production for the year was 59,587,000 barrels—16 percent less than the record of 70,761,000 barrels established in 1937. Production decreased in the majority of the fields. Notable exceptions were, however, Weathered, Cowley County; Gorham, Russell County; and Geneseo, Rose County.

[1] Oil and Gas Journal.

*Kentucky.*—Despite considerable buyer proration in 1938, production increased to 5,821,000 barrels from 5,484,000 in 1937. Drilling declined in the western fields in 1938; nevertheless, the initial discovered was four times as large as in 1937. Two new McClosky lime pools, both in Henderson County, were discovered in 1938. Drilling in the eastern part of the State increased in 1938, but a high percentage of the completions were gas wells, and the 150 oil wells brought in averaged only 15 barrels initial.

*Louisiana.*—Production in Louisiana rose to a new peak in 1938, when 94,812,000 barrels were produced compared with 90,924,000 barrels in 1937. The northern fields about held their own, a 5,000,000-barrel decline at Rodessa being balanced by a comparable gain elsewhere, hence the increase was in the coastal district. Drilling increased slightly, as a loss in the northern fields was outweighed by a gain in the coastal or salt-dome fields.

Only one new field—Cross Lake near Shreveport—was discovered in the northern district in 1938. Deep sand discoveries continued important at Cotton Valley, this field and Lisbon supplying most of the gain to compensate Rodessa's decline.

In the coastal district exploration continued apace, and about 20 new fields were discovered in 1938. This record surpassed even that of the Texas Gulf Coast. Drilling was carried deeper and deeper, the deepest producing well in the world at the close of the

Digitized by Google

year being one in the new Dulac field at about 13,260 feet. Extensions, flank production, and deeper sands too numerous to mention individually were found. The "Conroe trend" play was given a substantial boost by the discovery of flush Cockfield production at Bancroft, Beauregard Parish.

*Michigan.*—Production in Michigan reached a new peak of 19,211,000 barrels in 1938 compared with the previous record of 16,628,000 barrels in 1937. The several declines in Michigan crude-oil prices, totaling 35 cents or more per barrel, dimmed the enthusiasm for development work; nevertheless, the number of oil wells brought in—566—was only 20 less than in 1937.

About a half dozen new fields were uncovered in Michigan in 1938, most of them being in the southwest corner of the State in nearly virgin territory. Of the new fields, Bloomingdale, Van Buren County, was the most active, but Freeman-Redding, Clare County, yielded the largest wells and appeared to have the most promising future.

*Mississippi.*—The potentialities of Mississippi as an oil producer are still favorably considered in some quarters, but developments of 1938 did little to enhance them. There was no commercial production reported in 1938, and drilling yielded but 6 gas wells and 19 dry holes.

*Montana.*—Production in Montana declined materially in 1938 (from 5,805,000 barrels in 1937 to 4,907,000 in 1938) as exports of crude to Canada decreased from 1,950,000 barrels in 1937 to 356,000 in 1938. Drilling again declined severely, and only about half as many oil wells were completed in 1938 as in 1937. The only new oil discovery was a field about 5 miles north of the Cut Bank field.

*New Mexico.*—Owing primarily to relatively greater curtailment, the output of New Mexico declined from the 1937 peak of 38,854,000 barrels to 35,759,000 in 1938. The number of oil wells brought in dropped 14 percent from 1937, but the total initial of 1938 was hardly a third of what it was in the preceding year. The Monument field succeeded Eunice as the leading producer. The Vacuum field led in development work in 1938. Extensions to old fields were numerous, but new fields discovered were limited to one oil field, West Eunice, and one gas field that promised to develop into an oil field.

*New York.*—Field activity in New York in 1938 was depressed owing to the low prices; drilling declined severely and production decreased from 5,478,000 barrels in 1937 to 5,045,000 in 1938.

*Ohio.*—Drilling continued to decline in Ohio, and production still trended downward. The output in 1938 was 3,298,000 barrels, including 582,000 barrels from the Lima district, compared with 3,559,000 barrels in 1937.

*Oklahoma.*—Generally lower demand and a loss of markets to Illinois and possibly other States were the underlying factors in reducing production in Oklahoma from 228,839,000 barrels in 1937 to 174,882,000 in 1938.

The output of all the major fields fell in 1938, a decrease of about 20,500,000 barrels for the Oklahoma City field being largest and of about 14,000,000 barrels at Fitts being second. Many of the more prominent Wilcox sand areas declined 50 percent or more between 1937 and 1938. Much of the field work in 1938 was conducted in the greater Seminole district, hence production decline was comparatively small, from 49,772,000 barrels in 1937 to 42,182,000 in 1938.

[1] Oil and Gas Journal.

Hardly half as many oil wells were completed in 1938 as in 1937—986 against 1,852. Furthermore, the wells of 1938 were of much smaller average size; in fact, the total initial for 1938 (215,000 barrels) was the lowest in 29 years. Incentives for an active drilling campaign generally were lacking, hence many of the operators who had not

Digitized by Google

migrated to other States "marked time" in 1938 by working over old wells (not recorded as new completions) or testing shallow horizons, particularly in the greater Seminole district where they had been passed up in the haste to reach the prolific Wilcox zone.

Wildcatting in 1938 had considerable success, although no new large fields were uncovered. Considered the most important new field was Ramsey, Payne County, which, though small in area, yielded unusually large wells. Hillsdale, Garfield County, was considered an important find, as it extended the producing area of the State to the northwest and opened a large area to exploration. The Coyle and Meridian fields, Payne and Logan Counties, respectively, were 1938 Wilcox discoveries of considerable promise. Important among deep-sand developments was the drilling of about 40 wells in the old Cement field, Caddo County.

*Pennsylvania.*—The 30-percent decline in the average price of Pennsylvania Grade crude oil in 1938 greatly depressed field work in Pennsylvania. Oil wells completed in 1938 totaled about 45 percent below 1937. Production, which had increased steadily since 1931, dropped from 19,189,000 barrels in 1937 to 17,426,000 in 1938.

*Texas.*—Lower demand and introduction of the Saturday and Sunday shut-downs in Texas in 1938 caused the trend of production to turn downward, and 475,614,000 barrels were produced compared with the peak of 510,318,000 barrels in 1937.

No change was made in the Bureau's districts for Texas, which remain as follows: For the monthly publications—Panhandle, West Texas, East Texas proper, Rodessa, Gulf Coast, and "Rest of State"; for the annual chapter—Panhandle, North, West, Central, East, and South Texas, and the Gulf Coast. East Texas in the annual report includes East Texas proper and Rodessa, as well as Van and other fields in that part of the State.

Drilling declined materially in the Panhandle in 1938, and production decreased from 27,617,000 barrels in 1937 to 23,556,000 in 1938. All five producing counties shared in the decline. Natural-gas discoveries outranked oil discoveries in the Panhandle in 1938, as only one oil field was found.

The development of the K-M-A field of Wichita County overshadowed all others in the North Texas district in 1938. About 700 or 800 oil wells were completed in the field in 1938 for a total initial of about 600,000 barrels. Although drilling elsewhere maintained the pace of 1937, production at K-M-A and other fields was held down by proration so that the total output for the district was about the same as in 1937.

Wildcatters, greatly encouraged by the results of deeper drilling in recent years, continued active, and a score or more new productive spots were found in North Texas in 1938. Jones County, on the west edge of the district, led in new discoveries. Outstanding new fields were Steffens, Jones County; Holliday, on the Wichita-Archer County line; and Hull-Silk, Archer County, which had three distinct producing zones.

Production in the West Texas district in 1938 was 72,653,000 barrels, or only slightly under the 75,743,000 barrels produced in 1937. Drilling in 1938 was about 25 percent lower than in 1937, but was partly offset by a gain in the average initial.

[10] Included under "Other West Texas."
[11] Includes Westbrook and other fields in Glasscock, Howard, and Mitchell Counties.

About a dozen new fields in nearly as many counties were found in 1938. Among these, Dunes, Crane County, and Payton, Pecos County, were most prominent. The Wasson field of Gaines County and the Denver field of Yoakum County were joined, and future drilling promises to link up other productive spots into a field of 50,000 or more acres, the largest in the district. Prospecting in the Ordovician, an expensive type of recreation for wildcatters in West Texas, was generally disappointing in 1938.

Reduced allowables due primarily to the week-end shut-downs were responsible for a decline of production in the East Texas field proper from 170,673,000 barrels in 1937 to 152,143,000 in 1938. The average bottom-hole pressure, a factor in determining the allowable, decreased but slightly in 1938 and actually increased in the last few months of the year. The net drop was from about 1,123 pounds per square inch on January 1 to 1,110 on December 31. Drilling declined sharply, only 1,599 oil wells being brought in during 1938 compared with 2,252 in 1937. However, the average daily initial gain increased from 1,214 barrels in 1937 to 1,282 in 1938.

Production in the other fields of the East Texas district fell from about 40,000,000 barrels in 1937 to about 33,000,000 in 1938. Van bore the brunt of the decrease; the Rodessa and Talco fields produced nearly as much as in the previous year. Several distillate discoveries of questionable significance and one oil field—Navarro Crossing, Houston County—comprised the principal realization from exploration work in 1938.

The Central Texas district, including chiefly the fault-line pools, passed another quiet year, with no important discoveries and with production continuing its gradual decline. Several new fields were found in Bexar and other counties, but they were small.

The rapid rise of production in the South Texas district, often referred to as the Laredo district, was halted in 1938, and production dropped from 30,780,000 barrels in 1937 to just under 30,000,000.

Drilling activity was definitely off, but the number of discoveries probably increased. The principal discoveries in 1938 were along the "Jackson trend," although wildcatting along the Cockfield and Pettus trends yielded favorable results. The trend type of geology probably finds wider use here than anywhere else in the country. Of the new discoveries, South Alice (Jim Wells County), Sun (Starr County), and Kelsey (Jim Hogg County) appeared outstanding. Many of the new

Digitized by Google

fields were 4,000 to 5,000 feet deep, which would be shallow in some parts of the country but is considerably deeper than the average wildcat of this district 10 years ago.

The Texas Gulf Coast was the only district in the State that gained in output in 1938, its production rising from 114,702,000 barrels in 1937 to 115,303,000 in 1938. The small increase was related to changes in the allowables, because drilling and total initial declined as in the rest of the State.

Although Conroe suffered a severe recession in output in 1938 it continued to be far and away the most important producer in the district. The production of most of the old fields declined in 1938, gains at Hastings, Old Ocean, Friendswood, and other fields just offsetting the losses.

For the first time, the number and aggregate estimated importance of the new discoveries in the Texas Gulf Coast were surpassed in the Louisiana Gulf Coast. However, about a dozen new productive spots were uncovered in Coastal Texas, several of which were situated offshore. Of the new discoveries, Cedar Point, Eureka, and Fairbanks appeared outstanding.

*Utah.*—Field work in Utah in 1938 was devoted to natural gas, and the oil production was only 12,000 barrels.

*West Virginia.*—Conditions in West Virginia in 1938 favored continuance of the general decline in production evidenced for the last 25 years. The output in 1938 was 3,684,000 barrels compared with 3,845,000 in 1937. The number of oil wells completed declined materially, but the total initial increased.

*Wyoming.*—Production in Wyoming declined but slightly in 1938—from 19,166,000 barrels in 1937 to 19,004,000 in 1938. Wyoming was one of the few States in which drilling increased; 95 oil wells were completed in 1938 compared with 72 in 1937.

Production in the Salt Creek field continued its slow but steady decline. However, it still held a considerable margin over the second-ranking field, Lance Creek, whose production increased in 1938 following a markedly successful drilling program.

Several new oil and gas fields were discovered, but only one deserves mention here—the Cole Creek field, Natrona County, which produces from about 8,000 feet.

*Production of crude petroleum in Wyoming, 1933–37, by districts* [1]

## WELLS

Owing to the unsettled price situation, drilling for oil and gas declined materially in 1938 from 1937. Total completions in 1938 were about 27,400, or nearly 4,000 fewer holes than in 1937. Of the total completions in 1938 70 percent were oil wells, 8 percent gas wells, and 22 percent dry holes. Compared with 1937 these data indicate chiefly an increase in the ratio of failures (see fig. 4). There were 363,030 producing oil wells at the beginning of 1938, and allowing for the customary percentage of abandonments this total may have reached 374,000 by the end of the year. The average production per well per day, which had increased steadily since 1934, dropped from 9.8 barrels in 1937 to about 9.0 barrels in 1938.

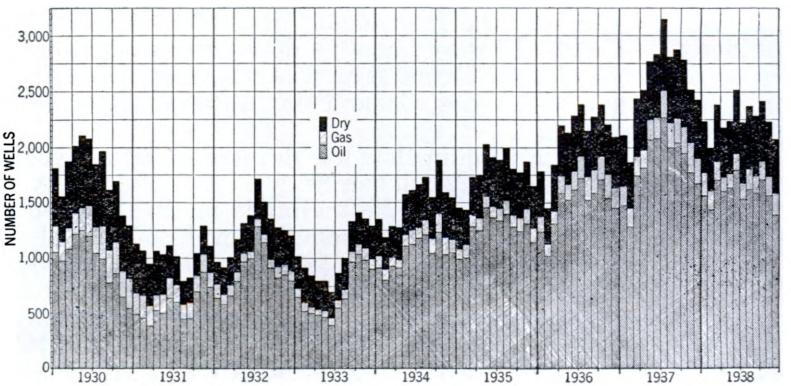

FIGURE 4.—Wells drilled, 1930–38, by months.

Although drilling declined materially in the East Texas field in 1938, it led in number of completions, with Wichita County in second place. The Bradford-Allegany district led in total number of holes drilled, but a large percentage were water-drive holes. The increases in field activity in several Illinois counties were the most spectacular developments in 1938.

## STOCKS

The trend of crude-oil stocks in the first quarter of 1938 gave every indication that the experience of 1937 would be repeated—that is, that stocks would be built up. However, drastic revisions in the allowables in April and May resulted in material declines in production. This allowed the expanding demand to catch up so that large withdrawals from stocks were made in May, June, July, and October and smaller ones in August, September, and November. Marked decreases in crude runs to stills during the year and exports in December resulted in an increase in stocks. The total for refinable grades on hand December 31, 1938, was 274,353,000 barrels compared with 305,091,000 on hand the first of the year. These totals are exclusive of stocks of unmixed heavy crude oil in California, segregated from fuel-oil stocks the first of the year, some of which is run to stills each month primarily to produce lubricants and asphalt. These stocks increased from 14,505,000 barrels the first of 1938 to 16,467,000 on December 31.

The net withdrawal from stocks of refinable grades of crude oil in 1938 was more evident in terms of days' supply than in quantity. The low point of days' supply for 1938 was 80, reached October 31—the lowest point in about 20 years.

Refinery stocks changed relatively little in 1938, the total rising about 500,000 barrels to 51,551,000 on December 31. Pipe-line and tank-farm stocks of Pennsylvania Grade crude oil increased materially, which contributed to the market weakness for this grade of oil. Substantial withdrawals were made from all the common grades of Mid-Continent crude oil. In 1938 pipe-line and tank-farm stocks in the Rocky Mountain district fell to the lowest point since 1923. The practice of converting surplus crude into products more easily stored was followed quite generally in California in 1938. However, although this held the increase in crude-oil stocks to under 6,000,000 barrels, stocks of products, mostly residual fuel oil, increased nearly four times that much.

Digitized by Google

Significant among the changes in crude-oil stocks by States of origin were the large withdrawals of oil originating in Oklahoma and Texas, an increase in Illinois oil, reflecting the new developments, and heavier reductions from the stocks of old oil in Wyoming. Stocks of foreign crude changed but little during 1938, the total at the close of 1938 being 3,521,000 barrels, or somewhat less than 2 months' supply.

## CONSUMPTION AND DISTRIBUTION

*Runs to stills.*—Total crude run to stills in 1938 declined over 18 million barrels from the record of 1,183 million barrels in 1937. The decrease was all in domestic crude runs as foreign crude runs remained virtually unchanged. Imports of Mexican crude were almost 2 million barrels less than in 1937, and imports from Venezuela increased slightly.

Crude runs in the Texas Gulf Coast district rose to 308 million barrels, an increase of 26 million barrels (9 percent) over 1937. The continued upward trend in this district presented the effects of increased refinery capacity and the very active export demand for refined products in 1938. The only other increase in runs was in the Rocky Mountain district a gain of 6 percent over 1937. All other districts declined from 1937. Compared to 1937 runs in the Texas Inland district decreased 11 percent, the East Coast district 9 percent, the Oklahoma, Kansas, and Missouri district 8 percent, the Louisiana Louisiana Gulf Coast district 8 percent, the Appalachian and Arkansas and Louisiana Inland districts 3 percent, and the Indiana, Illinois, Kentucky, and California districts 1 percent.

The material recession in the domestic demand for residual fuel oil was an important factor in the decrease in the runs to stills in 1938. Furthermore, efforts were being made in most districts east of California to liquidate the excess stocks of refined products accumulated in 1937. Many smaller refineries in inland locations were inoperative because of the relatively greater decline in the price of finished products compared to the price of crude petroleum. In California, the large increase in the stocks of finished oils, particularly residual fuel, indicated that runs were maintained at a far higher rate than demand warranted.

*Distribution.*—Receipts of domestic and foreign crude petroleum at refineries in the United States totaled 1,073 million barrels in 1936 and 1,191 million in 1937, but dropped to 1,167 million in 1938. Interstate receipts of domestic crude were 445 million barrels in 1938, compared to 487 million in 1937. This represented a relative decline in interstate shipments from 41 percent of the total receipts in 1937 to 38 percent in 1938. Intrastate receipts of domestic crude amounted to 696 million barrels in 1938 (60 percent of the total) compared with 676 million barrels (57 percent of the total) in 1937. Receipts of foreign crude fell 1 million barrels. The increase in the relative proportion of intrastate receipts continued the trend of recent years and reflects the growth in the local refining of Texas production in the Gulf Coast district. However, the trend was accentuated by a decline in runs in the East Coast district and the maintenance of excessive runs in California.

Refinery receipts of crude in 1938, by methods of transportation, indicated that 73 percent of the total was delivered by pipe lines, 24 percent by boat, and 3 percent by tank car and truck. Compared to 1937 the percentage of pipe-line shipments increased 2 percent, while shipments by boat dropped by about the same amount. The most important boat movement of crude is from Gulf ports to the East Coast. These shipments decreased from 171 million barrels in 1937 to 151 million in 1938.

Exports of domestic crude have increased steadily in recent years. The 77 million barrels exported in 1938 represented an increase of 10 million over 1937. Texas was the largest exporter in 1938, with 34 million barrels, followed by California, with 28 million, and Oklahoma, with 12 million.

Approximately 39 percent of the total movement of domestic crude petroleum from producing fields to refineries was interstate and 61 percent intrastate.

[5] Includes Rhode Island.
[6] Includes Idaho, Nebraska, and South Dakota.

Receipts of crude petroleum at refineries represent the principal data for determining the trend of market demand by States. In 1938 Texas, Oklahoma, California, Louisiana, Kansas, and New Mexico supplied about 90 percent of the refinery receipts of domestic crude compared to 92 percent in 1937.

Total refinery receipts of Texas crude decreased by 15 million barrels—from 460 million in 1937 to 445 million in 1938. Deliveries to refineries in Texas amounted to 299 million barrels (67 percent of the total) and increased almost 19 million barrels over 1937, while deliveries to refineries in other States declined by 33 million barrels. These figures indicate continuance of the trend to refine a larger proportion of State production in the Texas Gulf district. Exports of Texas crude amounted to about 34 million barrels, a gain of 4 million from 1937.

Domestic refinery receipts of Oklahoma crude decreased by 23 million barrels—from 207 million in 1937 to 184 million in 1938. Deliveries to Oklahoma refineries declined by only 4 million barrels compared to a decrease of 19 million barrels to other States. Exports of Oklahoma crude totaled about 12 million barrels, an increase of

Digitized by Google

over 3 million from 1937. The sharp decline in State production, although partly offset by a considerable liquidation of accumulated stocks of Oklahoma origin, indicates a relative decline in the market position of Oklahoma crude.

The deliveries of California crude to domestic refineries decreased slightly—from 206 million barrels in 1937 to 204 million in 1938. Normally, shipments are all intrastate, but in 1938 about 1 million barrels went to the East Coast district. The large increases in stocks of refined oils indicate that runs to stills were considerably above actual requirements. Exports of crude petroleum rose from 23 million barrels in 1937 to almost 28 million in 1938.

| Total United States | 460,045 | 445,251 | 206,894 | 184,163 | 85,286 | 84,459 | 66,836 | 60,668 | 39,631 | 44,282 |

There was little change in 1938 in the demand for Louisiana crude, as deliveries to domestic refineries continued at about 85 million barrels, and exports of crude were virtually the same as in 1937. An increase of 5 million barrels in crude delivered to refineries within the State about offset the decline in interstate shipments to other districts.

The market for Kansas crude declined, owing to the rise in production in Illinois and to eastward shipments from Wyoming. Deliveries of Kansas crude to refineries fell from 67 million barrels in 1937 to 61 million in 1938, and the decrease was divided about equally between intrastate and interstate deliveries.

The market for New Mexico crude continued to increase, but at a slower rate. Deliveries to refineries rose in 1938 to about 44 million barrels, an increase of 5 million. This increase was all in interstate shipments and mainly to the Texas Gulf Coast refinery district.

The total production of crude petroleum in Illinois rose to about 24 million barrels in 1938, an increase of about 16 million barrels. Deliveries of crude to refineries within the State rose from 5 to 8 million barrels, and large additional shipments were made to refineries in adjacent States. The rapid expansion in the supply of Illinois crude was a serious competitive factor in the markets formerly supplied by crude from more distant sources.

## PRICES AND VALUE

The average value of crude petroleum at wells, which increased in both 1936 and 1937, dropped in 1938, owing to the almost general price cuts, averaging about 15 cents per barrel, in the first half of October. The estimated value for 1938 is $1.15 per barrel compared with $1.18 in 1937. From the standpoint of historical interest the 1938 average ($1.15) was just under the averages of 1878 and 1928 and just over the average of 1899. Most of the other annual averages in the 60-year interval were lower.

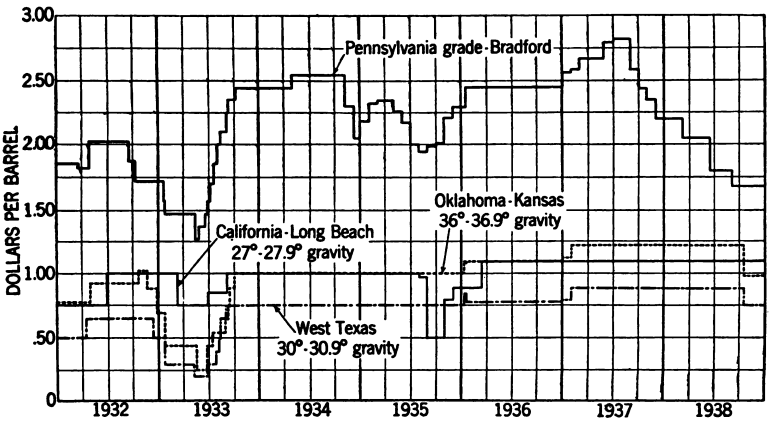

FIGURE 5.—Posted prices of selected grades of crude petroleum, 1932–38, by months.

The posted price of 36°–36.9° gravity crude in Oklahoma was $1.22 on January 1 but fell to $1.02 on October 12. This price of this grade of crude generally is used as a yardstick, although the average for the next heavier grade (34°–34.9°) in Oklahoma is generally closer to the national average.

Details of price changes for selected grades of crude petroleum are shown in the tables that follow and in figure 5.

## ROYALTIES ON INDIAN AND FEDERAL LANDS

On page 853 of Minerals Yearbook 1938 were given data up to 1937 on royalty receipts, bonuses, etc., pertaining to Indian and Federal lands. The acreage of new leases on Indian lands during the fiscal year 1938 was 99,187 compared with 155,503 (revised) in 1937. Bonuses from the sale of leases in 1938 were $239,293, royalty from production of oil and gas totaled $5,048,280, and advance royalty and annual rentals amounted to $502,664.

The production of crude petroleum on Government lands in the calendar year 1938 totaled 43,515,000 barrels, of which 5,369,000 barrels valued at $5,869,000 was royalty.

## REFINED PRODUCTS

Despite the general set-back in business conditions in 1938, petroleum refining was not affected nearly as much statistically as were many other industries. Domestic motor-fuel demand made a new record of 521,657,000 barrels, exceeding the 1937 demand by one-half of 1 percent, while the export demand increased 31 percent, making an increase of 2.5 percent in total motor-fuel demand.

Crude runs to stills dropped from 1,183,440,000 barrels in 1937 to 1,165,015,000 in 1938. Domestic demand for gas oil and distillate fuel oils was about the same as for 1937, and the demand for residual

Digitized by Google

fuel oils declined from 325,514,000 barrels to 292,650,000. The demand for kerosene and asphalt increased slightly, but the demand for lubricants, wax, coke, and road oil was less than for 1937.

Digitized by Google

The yield of gasoline reversed its downward trend to increase from 43.9 percent in 1937 to 44.3 in 1938. The yield of gas oil and distillate fuel oils also increased from 12.4 to 13.0, percent while that of the residual fuel oils decreased from 26.4 to 25.3 percent. (See fig. 6.)

Natural-gasoline production increased from about 49 million barrels in 1937 to about 50 million in 1938, but benzol production declined from 2,790,000 barrels in 1937 to 1,699,000 in 1938.

The total refinery output of gasoline in 1938 was about 556 million barrels, comprising about 245 million barrels of straight-run gasoline, 271 million barrels of cracked gasoline, and 40 million barrels of natural gasoline.

[2] Includes natural gasoline run through pipe lines in California.
[3] Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced.

These statistics, however, do not give a true picture of the distress brought to the industry by the recession. Domestic motor-fuel demand was halted in its upward sweep of early 1937, in the first 4 months of which it was more than 11 percent higher than for the same period in 1936. In contrast, the increase in the demand for the first half of 1938 was less than one-half of 1 percent over the demand for the same period of 1937. The inability of the industry to adjust its operations to the sudden change from the rapid upward trend to the retarded demand caused a large accumulation of stocks. Finished and unfinished gasoline inventories reached a peak of more than 92 million barrels, or 57 day's supply on March 31, 1938, compared with 82 million barrels or 51 day's supply on the same date in 1937. Stocks

Digitized by Google

of residual fuel oil increased from 78 million to 87 million barrels and distillate fuel oil stocks from 17 million to 19 million barrels during this same period.

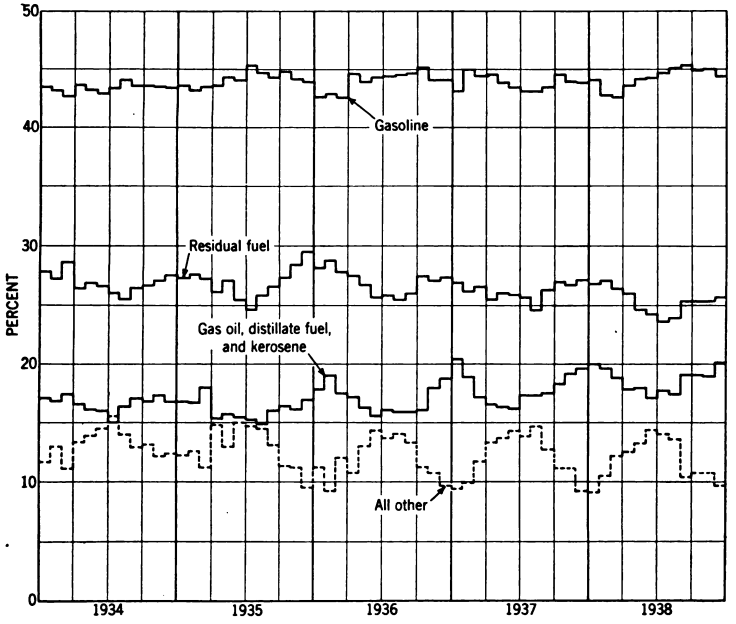

FIGURE 6.—Yields of principal petroleum products from crude oil run to stills, 1934–38, by months.

Prices dropped sharply. The refinery price for Oklahoma gasoline fell from a high of 6.19 cents per gallon in May 1937 to 4.90 cents in May 1938. (See fig. 7.) This represented a loss of more than 20 per-

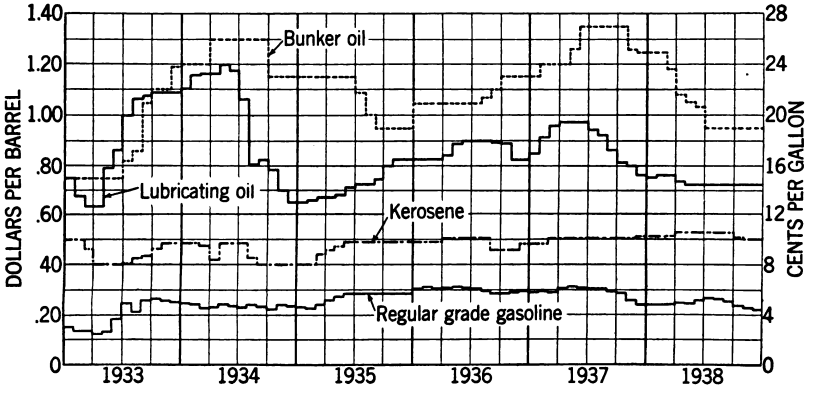

FIGURE 7.—Prices of refined petroleum products, 1933–38, by months.

cent for the year, whereas the Bureau of Labor Statistics index of wholesale prices of all commodities decreased only 11 percent during this period. Heavy fuel-oil prices dropped nearly 10 cents per barrel between the summer of 1937 and August 1938, while the prices of most lubricating oils declined.

[1] Details by districts and months in section on "Consumption and distribution of crude petroleum."
[2] Includes 1,374,000 barrels run through pipe lines in California in 1937 and 1,349,000 barrels in 1938.
[3] Negative quantity; represents net excess rerun over production.
[4] Negative quantity.
[5] Subject to revision.

[2] Includes benzol.

Although in 1936 and 1937 the number of refineries decreased, the total crude-oil capacity continued the upward trend, last interrupted in 1932. There were 551 completed plants on January 1, 1938, compared with 572 the previous year; the daily capacity of these plants rose from 4,294,881 barrels (old basis) on January 1, 1937, to 4,351,151 barrels (new basis) on January 1, 1938.

Digitized by Google

The operating ratio, or the percentage of crude runs to capacity, decreased from the relatively high figure of 83 for 1937 to 78 for 1938. The gain in total capacity of excess equipment in 1937 virtually silenced those who claimed that a shortage of some products was imminent, yet it was not enough to alarm those with contrary views. Although at the beginning of 1938 about 800,000 barrels of daily crude-oil capacity remained unused in the operating units besides about 250,000 barrels of idle equipment in "good shape" on that date, most of this is obsolete and constitutes little in the nature of a threat toward overrunning.

*Summary of refinery capacity in the United States, January 1, 1934–38* [1]

| Year | Number | | | | Capacity (barrels per day) | | | |
|---|---|---|---|---|---|---|---|---|
| | Operating | Shut down | Building | Total | Operating | Shut down | Building | Total |
| 1934 | 454 | 137 | 13 | 604 | 3,553,569 | 364,648 | 44,450 | 3,962,667 |

## MOTOR FUEL

Motor-fuel statistics for the year, with the exception of exports, did not differ greatly from those of 1937. Production and stocks at the end of the year were slightly less, and domestic demand was slightly

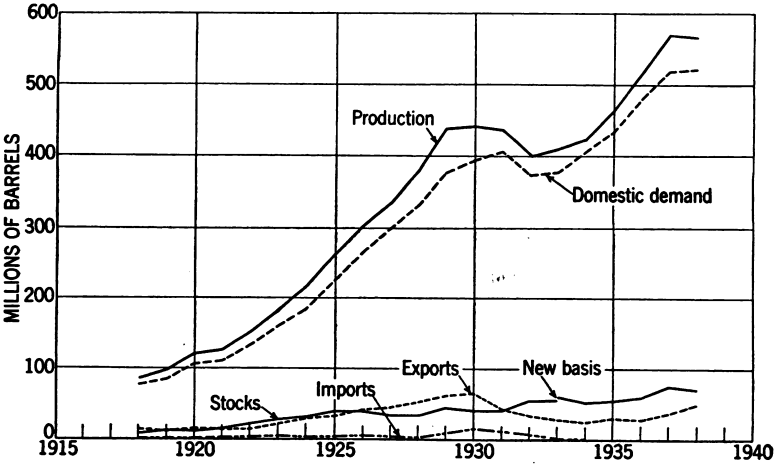

FIGURE 8.—Trends in production, domestic demand, exports, imports, and stocks of motor fuel, 1918–38.

more. Exports, however, showed an increase of 12 million barrels (31 percent). (See fig. 8.)

*Demand.*—The domestic motor-fuel demand in 1938 was 521,657,000 barrels, an increase of one-half of 1 percent over the 1937 record of 519,352,000 barrels. The demand for the first quarter increased 1.9 percent over that for the same quarter of the previous year, but in the months from April to September, inclusive, it was less than in the

Digitized by Google

corresponding months of 1937, the July and September figures declining 3.4 and 2.5 percent, respectively. The recovery in business conditions during the fall gave the last quarter of 1938 an increase of 4¼ percent over the last quarter of 1937 and brought the year's demand above that of 1937.

[1] Revised figures. [2] Subject to revision. [3] 89 percent of total motor-fuel demand.

New motor-vehicle registrations in 1938 dropped to 2,256,000 compared with 4,102,000 in 1937. Preliminary calculations of cars in use on July 1 as shown in the accompanying table indicate an increase of approximately 618,000 vehicles to 28,190,000 compared with 27,572,000 for July 1, 1937. Gasoline consumption per motor vehicle in use was 18.50 barrels for 1938 compared with 18.84 barrels for 1937.

The export demand for gasoline increased from 38,306,000 barrels in 1937 to 50,198,000 in 1938. Part of these exports undoubtedly have been for the purpose of building up stocks for military purposes, but because of the secrecy involved it is difficult to estimate how much has gone into such storage. It is almost a certainty, considering the greater number of motor vehicles and improved highways in foreign countries, that part of this increase in exports represents a permanent increase in demand and will remain a future market for the United States if not supplied by other sources. More detailed information on exports and imports is given in another section of this chapter.

Digitized by Google

*Production.*—Motor-fuel production was 3,822,000 barrels less than the 1937 figure of 571,727,000 barrels. The 1938 production of 567,905,000 barrels comprises 245,418,000 barrels of straight-run gasoline, 270,471,000 of cracked gasoline, 39,961,000 of blended natural gasoline, 10,356,000 of unblended natural gasoline, and 1,699,000 of benzol. The ratio of straight-run gasoline to total motor-fuel production continued its trend, dropping from 44.0 percent in 1937 to 43.2 in 1938, while that of cracked gasoline continued its increase, rising from 46.9 percent in 1937 to 47.6 in 1938. The ratio of natural gasoline increased from 8.6 percent in 1937 to 8.9 in 1938, while that of benzol declined from 0.5 to 0.3 percent. The decline of 39 percent in benzol production probably resulted from curtailing steel-mill operations, which dropped from an average of 61 percent of capacity in 1937 to 25 percent in 1938.

*Yields.*—The downward trend in gasoline yields was broken in 1938 when straight-run and cracked production comprised 44.3 percent of crude runs to stills compared with 43.9 percent in 1937. Almost one-half of this increase, however, represents a gain in production contributed by unfinished gasoline, stocks of which declined 1,616,000 barrels during the year.

The demand for increasingly better gasoline, both for automobiles and for airplanes, has put pressure on refiners to produce motor fuel with ever higher octane rating. Octane qualifications first appeared on October 19, 1931, when a 57–65 octane rating was required for regular-grade gasoline. This was changed on May 8, 1933, to 60–64 octane; on August 6, 1934, to 63–70 octane; on April 15, 1935, to 68–70 octane; and on April 20, 1937, to 67–69 octane. Army airplanes and many air-transport planes now require 100 octane fuel.

The two principal methods open to refiners for increasing the octane rating of their motor fuel are to add tetraethyl lead and to re-form. The loss by re-forming, or cracking, gasoline has been one of the most expensive losses, probably around 20 to 25 percent.

During recent years the polymerization process has been developing; it is somewhat the antithesis of cracking, whereby the lighter molecules, such as those of still gas and natural gas, are converted into heavier molecules to make gasoline. The principal source of charging stock for the polymerization units now in operation is the gas from the cracking stills. Although the quantity of gasoline produced by polymerization is extremely small, it has some influence toward raising gasoline yields.

Of importance for the future is the rapid development of new catalytic cracking processes, which increase the yield of the lighter products of petroleum considerably.

The yield of cracked gasoline continued its upward trend by increasing from 22.7 percent in 1937 to 23.2 in 1938, but the yield of straight-run gasoline remained virtually the same at 21.1 percent, 0.2 percent lower than in 1937.

During the early part of the year gasoline yields were low, dropping to 42.6 percent in March. From this point they rose steadily to 45.3 percent in September, a point that had not been exceeded since September 1933.

Among the districts, Inland Texas is noteworthy because of its continuous upward trend, the yield having increased approximately 6 percent in the last 3 years. The 1938 yield was 54.0 percent compared with 51.2 percent in 1937.

Digitized by Google

*Prices.*—The average refinery price per gallon of regular-grade Oklahoma gasoline for 1938 was 4.90 cents compared with 5.81 cents in 1937 and 5.95 in 1936. The price at the beginning of the year was 4.75 cents and rose to a peak of 5.38 cents during the summer, but subsequently declined to close the year at 4.38 cents.

The average service-station price of regular-grade gasoline (ex-tax), as compiled by the American Petroleum Institute, dropped from 14.58 cents per gallon in 1937 to 14.07 cents in 1938. The price on January 1—14.29 cents—was the highest of the year, from which it declined almost every month to reach a low of 13.32 cents on January 1, 1939.

The greatest change in price (3.5 cents) was in Salt Lake City, Utah, where the price slid from 18.5 cents on January 1, 1938, to 15.0 cents on January 1, 1939. Louisville, Ky., with a change of 2.3 cents—from 14.0 cents to 11.7—was next in magnitude, and New York City and Hartford, Conn., followed with changes of 2.0 cents each. The Atlantic Coast area, with an average price decline of 0.81 cents, suffered the heaviest slump. This group, however, includes Philadelphia, where the 1.5-cent price increase from 11.75 to 13.25 cents was the greatest of any city.

In general, the Rocky Mountain States had the highest gasoline prices with averages ex-tax, at the beginning and closing of the year, of 16.75 and 16.25 cents, respectively. Boise, Idaho, with a price of 25.5 cents per gallon, including 6 cents in taxes, had the highest price of any city on January 1 but dropped out of that position during the year. Spokane, Wash., and Helena, Mont., where gasoline sold for 24 cents per gallon, including 6 cents in taxes, had the highest prices at the end of the year, and New Orleans came next with a 23.5-cent price, including 10 cents in taxes.

Wichita, Kans., had the lowest-price gasoline at 14.1 cents per gallon, including 4 cents in taxes, which was effective the last half of the year. However, as a group, the North Atlantic Coast States had the lowest prices. The averages for this section at the beginning and the end of the year were respectively, 12.83 and 12.02 cents, extax. Springfield, Mass., and Providence, R. I., in this group, where gasoline sold for 15 cents per gallon, including 4 cents in taxes, had the next lowest price to Wichita.

The posted price, however, is not necessarily the price the customer pays for his gasoline, discounts of 1 to 3 cents per gallon being customary in many parts of the country. Several attempts have been made to stop price cutting. It was prohibited in the oil code of N. R. A. days. The Wisconsin State Department fixed minimum prices for gasoline in 1934, and Iowa and Pennsylvania passed price-posting laws in 1937, while a similar law was vetoed in Illinois. California, in the same year, not only amended her Unfair Practices Act and Unfair Trade Act to strengthen oil marketing, but also her Oil Substitution Act originally passed in 1931 and amended in 1933, to require the posting and maintenance of the actual selling price. New Jersey passed a price-posting law that became effective June 1, 1938, which is a companion to the law permitting resale-price maintenance contracts between the dealer and service-station operator.

Although the difficulty of obtaining convictions under these acts has raised some question as to their effectiveness, a recent favorable decision in the Superior Court in Los Angeles has been followed by a number of arrests in California. Reports indicate that the New Jersey law has improved the price situation in that State. A few

Digitized by Google

convictions have been obtained, but the cases were not appealed, so there has been no real test of the law as yet.

The 50-city average dealer's net price—10.18 cents on January 1, 1938—declined steadily throughout the year. However, the average price of 9.56 cents on January 1, 1939, was only 0.62 cent lower than that at the beginning of the year. The yearly average was 10.43 cents compared with 10.53 cents for 1937.

The year 1938 was the first in which there was no change in gasoline taxes, with the possible exception of some local levies in the less important places. State taxes remained at an average of 4.44 cents per gallon throughout the year, and the 1-cent Federal tax was in effect throughout the year. In addition to these taxes, there were numerous municipal and county taxes.

During 1938 one State (Missouri) and the District of Columbia had a tax rate of 2 cents, 10 States a tax rate of 3 cents, 18 States a tax rate of 4 cents, 10 States a tax rate of 5 cents, 5 states a tax rate of 6 cents, 1 State a tax rate of 6½ cents, and 3 States a tax rate of 7 cents.

*Stocks.*—Finished gasoline stocks totaled 65,949,000 barrels on December 31, 1938, 3,943,000 barrels less than on December 31, 1937. None of the districts had greater stocks than at the close of 1937. The largest decrease was in the East Coast district, which declined 1,024,000 barrels compared with an increase of 4,000,000 barrels in 1937.

Digitized by Google

Stocks of gasoline began to increase abnormally fast late in 1937 and reached a record peak at the end of March 1938 when stocks, including 7,285,000 barrels of unfinished gasoline, amounted to 92,320,000 barrels. Although crude runs to stills were greater than was considered desirable, they were restricted enough to reduce stocks almost to a normal level by the end of the year. Referring to the table of days' supply of motor fuel on hand it may be seen that the peak stocks at the end of March 1938 were 5.3 days' supply more of finished gasoline than those for March 31, 1937. As the year progressed, however, days' supply of gasoline approached nearer normal.

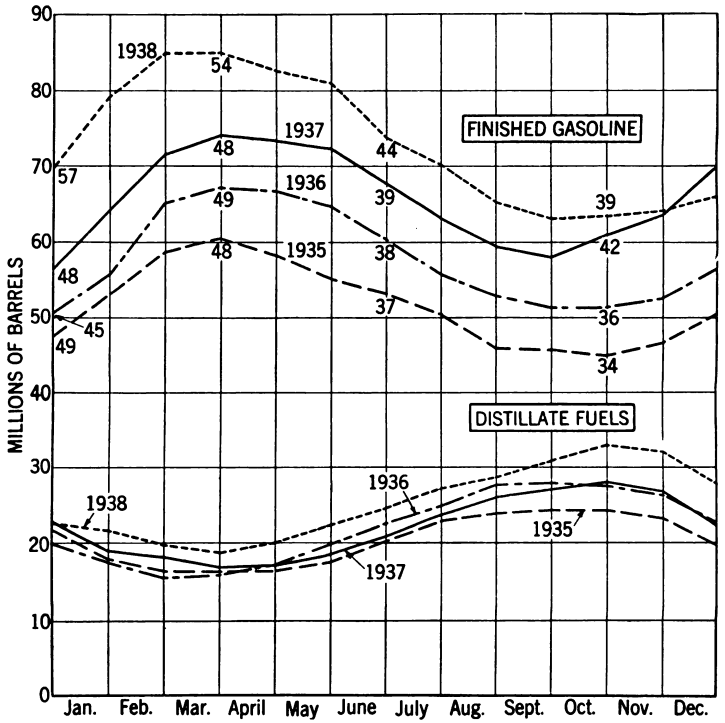

FIGURE 9.—Stocks of finished gasoline and distillate fuels, 1935–38, by months.

until on December 31, it was less than 2 days more than on December 31, 1936 and over 7 days less than on December 31, 1937.

Seasonal variations in gasoline stocks in recent years are shown in figure 9, which gives the quantity of finished gasoline stocks in millions of barrels for the last day of each month from December 1934 to December 1938, together with equivalent days' supply at certain periods. The figures for days' supply on the chart represent the quantity of finished gasoline on hand at the end of a month divided by the total demand for the succeeding month; they are the same as shown in the accompanying table.

Figure 9 also includes stocks of distillate fuels for the same period to bring out the contrast in seasonal variations in stocks of the two products. It may be seen that distillate fuel stocks were materially higher in 1938 than in the 3 previous years, particularly in October, November, and December.

[1] Stocks divided by the daily average total demand (domestic demand plus exports) for succeeding month.
[2] Subject to revision.

*Production by States.*—Texas led in the production of gasoline, with the output of 182,427,000 barrels or 33 percent of the United States total, compared with only 30 percent in 1937. California, Pennsylvania, Indiana, and Oklahoma followed with 14, 8, 7, and 6 percent, respectively.

*Consumption by States.*—New York still leads in gasoline consumption in 1938, but it declined in relative importance in 1938. New York and California consumed about 8 percent each of the total, Pennsylvania 7 percent, and Illinois, Ohio, and Texas 6 percent each. (See fig. 10.)

*Distribution.*—The amount of motor fuel transported by pipe lines increased from 73,233,000 to 85,297,000 barrels (16 percent). Compared with the 2.5 percent increase in total motor-fuel demand, these statistics indicate that the tendency for the proportion of gasoline transported by pipe lines to increase is continuing.

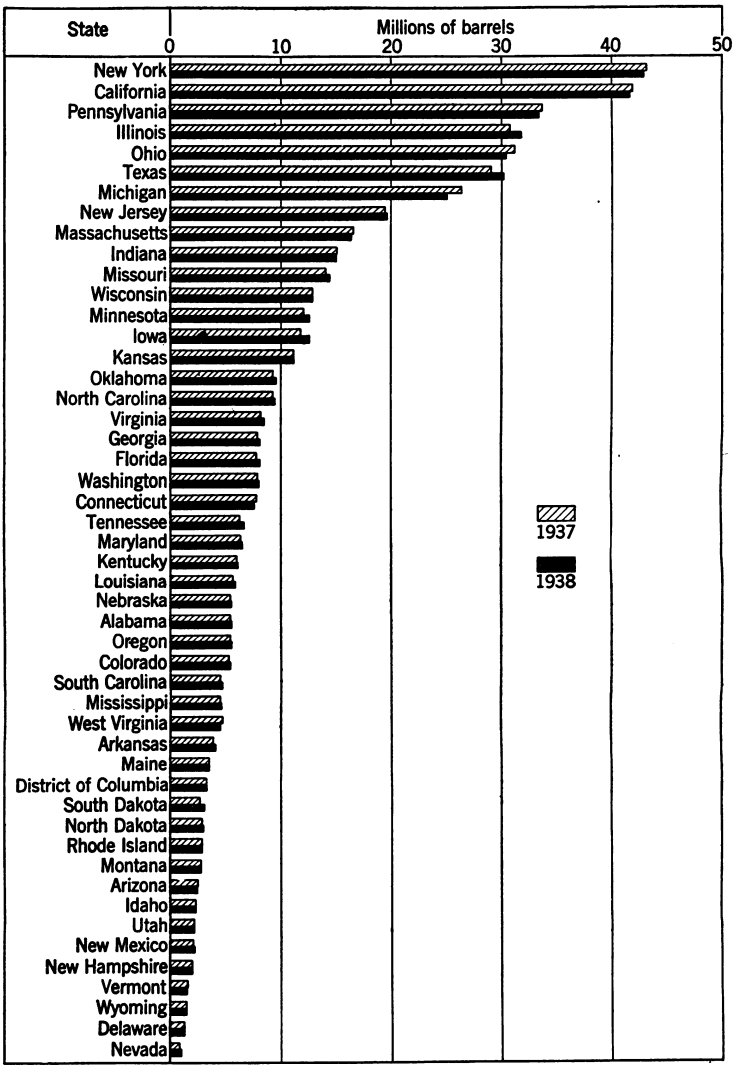

FIGURE 10.—Gasoline consumption, 1937–38, by States.

Boat shipments of gasoline from California to the East coast decreased from 4,144,000 barrels in 1937 to 2,965,000 in 1938, but the tanker movement from the Gulf coast to the East coast, which includes virtually all of the gasoline movement between these points, rose from 104,127,000 barrels in 1937 to 105,036,000 in 1938.

A comparison of prices at Gulf coast points and New York Harbor is interesting in connection with this movement. During 1937 the average price of gasoline in New York was 0.05 cent less per gallon than the average Gulf coast price plus the tanker rate to New York. In 1938, however, the average price of gasoline in New York was 0.66 cent more than the average Gulf coast price plus the tanker rate, and in December 1938 it was 0.71 cent more. The accompanying table shows these relationships in more detail.

## KEROSENE AND RANGE OIL[2]

Kerosene statistics for 1938 show increased domestic demand and higher year-end stocks than in 1937, but production and exports in 1938 were below the 1937 totals. The production of kerosene dropped from 65,308,000 barrels in 1937 to 64,580,000 in 1938. This lower output of kerosene can be attributed to the running of slightly less crude oil to stills, as there was no change in the percentage of kerosene yield, which averaged 5.5 percent for both years. Domestic demand for kerosene increased from 54,972,000 barrels in 1937 to 56,351,000 in 1938, or by less than 3 percent, a gain somewhat below the average for recent years. A review of the kerosene domestic demand figures by quarterly totals reveals that a gain in the first quarter of 1938 over the same period of 1937 about equaled the net increase of 1,400,000 barrels for the entire year. Furthermore, demand in the second quarter of 1938 declined about 700,000 barrels in comparison with the same quarter of 1937, but this loss was made up by nominal gains realized in the closing quarters of the year.

Kerosene stocks increased from 7,083,000 barrels at the end of 1937 to 7,799,000 at the close of 1938. The 700,000 barrels of kerosene added to storage in 1938 is approximately half the stock increase in 1937. The smaller amount added to stocks in 1938 is directly connected with the lower production of kerosene for that year, as a gain of about 1,400,000 barrels in domestic demand was offset by a similar loss in exports.

Exports of kerosene dropped from 8,886,000 barrels in 1937 to 7,513,000 in 1938, the first decline in overseas trade since 1935. Many countries required less American kerosene in 1938 than in 1937; however, purchases by Denmark, Sweden, the United Kingdom, Canada, and the Philippines gained in 1938.

Annual surveys prior to 1937 covered only that portion of kerosene sold as range oil; however, petroleum refiners and jobbers were requested to report to the Bureau of Mines for 1937 all kerosene deliveries by States and principal uses. The 1937 returns show kerosene sales of 54,551,000 barrels, divided as follows: Sold as range oil, 30,099,000 barrels; tractor fuel, 4,251,000 barrels; and all other uses, 20,201,000 barrels.

*Sales of range oil in the United States, 1935–37, by States* [1]

[1] Figures for 1938 by States not yet available.

In recent years, as the demand for range oil has expanded rapidly, some No. 1 fuel oil has been sold for range fuel, replacing kerosene. In 1937, the fuel oil delivered for range fuel was reported as a separate item for the first time, and final figures show range-oil sales of 32,580,000 barrels, comprising 30,099,000 barrels of kerosene and 2,481,000 barrels of No. 1 fuel oil. Range-oil sales were 27,292,000 barrels in 1936, and it is estimated that about 2,000,000 barrels of the total was No. 1 fuel oil and the balance kerosene.

[1] Estimated.

An upward trend in representative kerosene prices evidenced in recent years continued into 1938. There was, however, only a moderate advance in the Oklahoma refinery price, which averaged 4.19 cents per gallon in 1938 compared with 4.17 cents per gallon in 1937 and 3.69 cents per gallon in 1936. The average monthly quotations show high levels of 4.31 cents per gallon for both January and July and a low price of 4.04 cents per gallon in October, followed by an advance to an average of 4.09 cents per gallon for December.

The increase in the tank-wagon price, represented by quotations at Chicago, was more pronounced, as the average advanced from

Digitized by Google

10.04 cents per gallon in 1937 to 10.31 cents per gallon in 1938. A tank-wagon price of 10.2 cents per gallon ruled until late in March of 1938, when the quotation was raised to 10.5 cents per gallon to cover a 10-percent freight-rate increase in that marketing area. This higher price held until October, when the quotation dropped to 10 cents per gallon, where it remained until the end of the year.

## FUEL OILS[2]

The domestic demand for light or distillate fuel oils used principally for heating purposes remained at the same level in 1938 as in 1937; due largely to the decline in industrial consumption, however, the requirements for residual fuel oils fell sharply in 1938 compared with the record deliveries in 1937. Exports of fuel oils continued to expand in 1938 and established a new all-time record. The production of distillate fuel oils increased in 1938 over 1937; but the new supply of residual fuel oils, as measured by production, crude oil transferred to the fuel-oil account, and imports, reflecting the contracted demand for industrial fuel in 1938, declined sharply. The increase in fuel-oil stocks in 1938 was double the quantity added in 1937.

Domestic deliveries of fuel oils dropped from a record of 442,355,000 barrels in 1937 to 409,214,000 in 1938. The domestic demand for distillate fuel oils held in 1938, notwithstanding unfavorable economic conditions, because of heating-oil requirements and deliveries totaled 116,564,000 barrels or about the same quantity as in 1937. The inactive demand for industrial fuel caused the market for residual fuel oils to slump sharply in 1938; consequently, domestic requirements of 292,650,000 barrels were lower by 10 percent than the 1937 total of 325,514,000 barrels.

An examination of fuel-oil deliveries in 1938 by quarters compared with 1937 reveals that the demand for distillate fuel oils declined by 3 percent in each of the first two quarters of 1938 but that in the third quarter there was a gain of 8 percent over the corresponding 1937 period. This improved market did not hold, however, and the deliveries in the closing 3 months of 1938 were slightly below the requirements in the same quarter of 1937. Deliveries of residual fuel oils show serious losses for most of 1938 compared with 1937. This decline dipped to 17 percent in the second quarter of 1938 but was less marked thereafter, and the year closed with a 3-percent gain in the fourth quarter of 1938 compared with the final quarter of 1937.

The sharp decline in the demand for residual fuel oils in 1938 may be ascribed partly to the smaller purchases by Class I railroads reported by the Interstate Commerce Commission. The railroads, important users of heavy fuel oils, bought 57,955,000 barrels of fuel oils (including Diesel fuel) in 1938, or 16 percent less than the 69,292,000 barrels required in 1937. The Bureau of Foreign and Domestic Commerce, United States Department of Commerce, reports that vessels engaged in foreign trade loaded 33,983,000 barrels of bunker oil in 1938, 6 percent less than the 36,129,000 barrels loaded in 1937. Fuel-oil purchases by public-utility power plants compiled by the Federal Power Commission were 13,039,000 barrels in 1938—8 percent below the 1937 total of 14,143,000 barrels. If the present known items covering railroad, foreign bunker, and public-utility power-plant purchases of fuel oils in 1938 are subtracted from the indicated domestic demand for fuel oils in 1938, it is found that the remaining quantity available for all other uses, such as coastwise bunkers, industrial fuel, heating of buildings, Government requirements, and oil-company consumption in connection with petroleum production and refining, is 304,237,000 barrels for 1938 compared with 322,791,000 barrels for 1937. It is believed that the Bureau's annual fuel-oil survey for 1938 when completed will reveal that the larger portion of this loss is confined to the quantity used by smelters, mines, and manufacturing plants, due to their retarded operations in that year.

Figure 11 illustrates the trend in fuel-oil sales by principal uses, 1926–37. The sales include all grades of light and heavy fuel oils, as well as kerosene sold as range oil.

Digitized by Google

Exports of fuel oils, including shipments to noncontiguous Territories of the United States, increased from 45,433,000 barrels in 1937 to 47,631,000 in 1938. The upward trend in fuel-oil overseas trade, which began in 1933, continued into 1938, when the domestic demand declined; in fact, the 1938 export total of 47,631,000 barrels is an all-time record, surpassing the former record attained in 1927 by a quarter of million barrels. The gain in exports in 1938 was limited to the heavy or residual grades, which increased from 15,304,000 barrels in 1937 to 17,728,000 in 1938. Exports of distillate fuel oils

totaling 29,903,000 barrels in 1938 are approximately 1 percent under the 1937 quantity (30,129,000 barrels).

Germany and the United Kingdom increased their purchases of American distillate fuel oils in 1938 over 1937, while other important buyers, such as Japan, Netherland West Indies, Belgium, and Sweden, required less in 1938 than in 1937. The light fuel-oil trade with Japan totaled 5,297,000 barrels in 1938, a quantity about a million barrels below 1937 requirements.

Smaller exports of residual fuel oils to Japan, Chile, and Mexico in 1938 compared with 1937 were more than offset by increased shipments in 1938 to a number of countries, including Netherlands, United Kingdom, Italy, Spain, Canada, Cuba, Panama, and the Philippines. Residual fuel-oil exports to Japan decreased from 4,045,000 barrels in 1937 to 3,030,000 in 1938; however, this loss was more than counterbalanced by a gain in heavy fuel-oil shipments to Cuba, which increased from 247,000 barrels in 1937 to 1,356,000 in 1938. Further information on exports is given in the section entitled "United States Trade."

[1] Includes some crude oil burned as fuel.
[2] Figures for 1938 not yet available.

Crude oil runs to stills in 1938 totaling 1,165,015,000 barrels represents a decline of less than 2 percent compared with the 1937 throughput of 1,183,440,000 barrels; however, the production of fuel oils changed by nearly 3 percent, decreasing from 458,770,000 barrels in 1937 to 446,746,000 in 1938. The lower yield of fuel oils in 1938 represents a net loss, as the distillate fuel-oil output increased—probably in anticipation of an expanding demand for heating oils—by nearly 4 percent, or from 146,706,000 barrels in 1937 to 151,774,000 in 1938, while the production of residual fuel oils was reduced, because of slackened market demand, by over 5 percent, totaling 294,972,000

Digitized by Google

barrels in 1938 compared with 312,064,000 in 1937. The increased production of light fuel oils and the cut in the heavy fuel-oil output in 1938 were brought about largely by varying the average yield factors, which for the distillate grades increased from 12.4 percent in 1937 to 13.0 in 1938, whereas the average yield for residual fuel oils was reduced from 26.4 percent in 1937 to 25.3 in 1938.

[1] Subject to revision.
[2] Revised figures.
[3] Figures not available.

The Texas Gulf Coast was the only important refining area to show a gain in the production of fuel oils in 1938, the output increasing from 112,608,000 barrels in 1937 to 121,303,000 in 1938. There was, however, little change in that area in the yield of residual fuel oils, which amounted to about 73,000,000 barrels for both 1937 and 1938, while the distillate grades increased from 39,385,000 barrels in 1937 to 47,529,000 in 1938. California refineries, the chief source of residual fuel oils, are credited with a fuel-oil production of 115,024,000 barrels in 1938 compared with 116,665,000 barrels in 1937. Both light and heavy fuel oils were produced in reduced quantities in the East Coast region in 1938, the total yield declining from 85,294,000 barrels in 1937 to 79,281,000 in 1938. The Indiana-Illinois area produced 40,716,000 barrels of fuel oils in 1938, 1,300,000 barrels less than the 1937 output. In that territory a small gain in the production of distillate fuel oils was offset by a decline in the yield of residual fuel oils from 24,953,000 barrels in 1937 to 23,319,000 in 1938.

Digitized by Google

In the California area some crude oil, below standard for refining purposes, is transferred each year to the fuel-oil account. These transfers increased steadily as the demand for fuel oils developed, reaching a peak of 17,423,000 barrels in 1937 but dropping to 10,660,000 barrels in 1938. This decrease in the transfer of crude oil to the fuel-oil supply in 1938 apparently is associated with the lower demand for heavy fuel oils, as the non-gasoline-bearing crude available for fuel oil use was several times the quantity actually shifted to the fuel-oil inventory. Furthermore, the price of crude oil in California remained virtually unchanged during 1938 compared with a drop from $1.00 to $0.80 per barrel for heavy fuel oil, so that there was less incentive to make transfers from crude to the fuel-oil account.

The supply of fuel oils was augmented by imports in 1938 of 20,985,000 barrels compared with 22,131,000 barrels in 1937. Nearly all this fuel oil originated in the Netherland West Indies, and the larger share was entered at the Port of New York. Most of the fuel oil imported is received in bond and is released later for the bunkering of vessels, without payment of import duty. There were no imports of distillate fuel oils in 1938. Imports of residual fuel oils in 1937 and 1938 were classified as follows—18,081,000 barrels received in bond in 1938 compared with 19,613,000 in 1937, and duty paid for domestic use on 2,904,000 barrels in 1938 and 2,501,000 in 1937.

Curtailed domestic demand caused fuel-oil stocks to increase heavily in 1938, when over 21,500,000 barrels were added to storage compared with a gain in stocks of 10,500,000 barrels in 1937. As of January 1, 1938, stocks of unmixed heavy crude in California were separated from other fuel-oil stocks. On the new basis, the gain in residual fuel-oil stocks for the United States as a whole in 1938 was 16,239,000 barrels compared with a gain of 10,783,000 barrels in 1937. Stocks of distillate fuel oils increased by 5,307,000 barrels in 1938 in contrast to a decline of 247,000 barrels in 1937.

The gain in 1938 of 5,300,000 barrels in distillate fuel-oil stocks was divided about equally between the California area, with an increase of 2,700,000 barrels, and the rest of the country, where 2,600,000 barrels were added to storage. The more important changes in light fuel-oil stocks in 1938, outside of California, occurred in the Indiana-Illinois refining area, where approximately 900,000 barrels were added; the East Coast district, with a gain of about 700,000 barrels; and the Texas Gulf Coast district, with an increase of 400,000 barrels.

The major stock increase for 1938 is for the California area, where approximately 16,600,000 barrels of residual fuel oils were added to storage during the year, largely as a result of lower domestic and export demand. Heavy fuel-oil inventories in refining areas other than California made a net decline of about 400,000 barrels in 1938. There was a shrinkage of 1,400,000 barrels in the volume of residual fuel oils held in the Louisiana Gulf Coast district and smaller stock losses for the Appalachian and Indiana-Illinois areas. All other districts east of California showed gains in heavy fuel-oil stocks for 1938; the larger increase was in the Oklahoma-Kansas-Missouri group of States, where over 600,000 barrels of residual fuel oils were added to storage.

[2] Subject to revision.
[3] Stocks on new basis; corresponding United States total for January 1, 1938, 81,507, and for California, 54,144.
[4] Figures not available.

Monthly refinery reports reveal a shipment of 59,000 barrels of residual fuel oil from California to the East coast in October, 1938, which may be significant, as it is the first heavy fuel-oil movement in that direction since November 1934. Similar shipments appear for November and December 1938, making a total of 338,000 barrels for the year. The market price of heavy fuel oil on the Pacific coast plus tanker rates do not apparently justify such movement at this time; however, the need for additional outlets for California heavy fuel oil and possible anticipation of a rising demand for industrial fuel oils in the eastern area, where excessive stocks are not a factor, may all be underlying reasons for revival of this trade. The shipment of distillate fuel oils from California to the East dropped from 726,000 barrels in 1937 to 321,000 in 1938.

The movement of distillate fuel oils from the Gulf coast to eastern ports increased from 27,452,000 barrels in 1937 to 29,187,000 in 1938, while the transfer of residual oils changed but slightly, totaling 56,987,000 barrels in 1938 and 56,891,000 in 1937.

The price of fuel oils showed a marked downward trend in 1938 due more to an inactive market demand than to the influence of changing crude-oil prices, which were fairly well maintained at an average of $1.15 per barrel in 1938 compared with $1.18 per barrel in 1937. A review of refinery and market prices in all sections of the country discloses, with few exceptions, lower quotations for fuel oils at the end of 1938 than at the close of 1937.

Lower tanker rates forced a reduction in the New York price of Bunker C fuel oil on March 11, 1938, from $1.25 to $1.15 per barrel

Digitized by Google

and a relative decline in the quotation at Gulf coast points to $0.85 per barrel. Bunker C fuel oil in the Pacific market dropped from a February average of $0.99 per barrel to a March average of $0.96 per barrel. A further decline of 10 cents per barrel in the price of Bunker C at Atlantic coast points became effective April 5, 1938, making the New York quotation $1.05 per barrel. Still lower tanker rates and a competitive market due to reduced industrial demand were given as the reasons for the price cut. At this time Bunker C was reduced by only 5 cents per barrel to $0.80 on the Gulf coast, while Pacific coast prices showed no reaction until early May, when the average quotation declined from $0.95 to $.89 per barrel. There was a general reduction in the price of light and heavy fuel oils along the Atlantic seaboard during the week ending June 25, 1938, due to a slackened demand and mounting stocks. Bunker C fuel oil at New York was dropped from $1.05 to $0.95 per barrel, and this price held until the end of the year. The Gulf coast quotation, reflecting this general reduction, declined by 5 cents to $0.75 per barrel; however, there was no general change in the Bunker C price in the California marketing area until early August, when the price dropped to $0.80 per barrel for the balance of 1938.

[2] Figures not quoted.

Digitized by Google

Retail price quotations for heating oils, as compiled by the Bureau of Labor Statistics, United States Department of Labor, exhibit the general downward trend of fuel-oil prices in 1938. The Chicago retail price for No. 2 heating oil was quoted at an average of 7.21 cents per gallon during the first half of 1938; however, by the opening of the heating season in September it had fallen to 7.08 cents per gallon. December average prices show a slight upturn to 7.15 cents per gallon for the Chicago market. The New York retail price for No. 2 heating oil dropped steadily during the year, from 7.65 cents per gallon in December 1937 to 6.60 cents per gallon in December 1938.

## LUBRICANTS

The domestic demand for lubricants declined 9 percent, from 23,323,000 barrels in 1937 to 21,248,000 in 1938. Most of the decline was in that used for industrial purposes, which dropped from 10,483,000 to 8,700,000 barrels (17 percent). The accompanying table shows estimates of the proportions of lubricating oil used for automotive and industrial purposes.

Exports of lubricants declined 14 percent, or from 10,975,000 barrels in 1937 to 9,402,000 in 1938, making a decrease of approximately 11 percent in total demand.

Production of lubricants declined from 35,321,000 to 30,826,000 barrels. The East Coast and the Texas Gulf Coast districts each produced 24.7 percent of this total. This is the largest proportion that the Texas Gulf Coast district has supplied during the past 10 years, while the figure for the East Coast district is the lowest of a 10-year downward trend. Aside from these developments, production statistics by districts show no significant changes.

[2] Revised figures.
[3] Figures not available.

Stocks of lubricants—7,695,000 barrels on December 31, 1938—were 183,000 barrels higher than on December 31, 1937. The largest gain was in the Texas Gulf Coast area, where they increased 404,000 barrels to total 1,810,000 barrels. Stocks also increased in the California, Appalachian, and Louisiana Gulf Coast areas but declined in the other districts.

Lubricating-oil prices in general did not change greatly in 1938 after their precipitous drop in 1937. A Pennsylvania neutral selling for 18.75 cents in early January slumped to 13.00 cents in June but subsequently recovered to 15.5 cents in December. Pennsylvania steam-refined cylinder stocks that sold for 7.75 cents in early January rose to 9.00 cents in the late spring and were selling at 8.00 cents at the close of the year. The price of Gulf Coast neutral oil that sold for 8.50 cents in January encountered a persistent downward trend and had drifted to 7.63 cents in December.

159434—39——64

Digitized by Google

There is a pronounced difference in the long-term trends in the prices of lubricating oils. The average prices in 1938 of the Oklahoma, Pennsylvania, and Gulf Coast neutrals used in the accompanying table were 94, 77, and 73 percent, respectively, of their 1930 averages, while the average prices in 1938 of Oklahoma bright stock and Pennsylvania cylinder stock were 49 and 53 percent of their 1930 averages. This is probably a result of the modern automobile requiring a lighter grade of oil than the one of a few years ago, which has changed the basic requirements for oil compounding from a major proportion of bright stocks to one of neutrals.

## OTHER PRODUCTS

### WAX

Domestic demand for wax decreased for the second successive year from 297,288,000 pounds in 1937 to 278,060,000 in 1938. Exports also declined from 231,723,000 to 201,919,000 pounds, making the total demand for wax in 1938, 9 percent less than it was in 1937. Production slumped 17 percent to 435,400,000 pounds, imports dropped 22 percent, and stocks on December 31 fell 11 percent to 129,340,000 pounds.

Digitized by Google

Wax prices were much weaker than is indicated by the year's average of 2.23 cents per pound compared with the 1937 average of 2.82 cents. The price per pound declined rapidly early in the year from 2.85 cents at the end of December to 1.93 cents in April, a drop of 35 percent from the high of August 1937. Subsequently it recovered to 2.40 cents and was 2.32 at the end of the year.

## COKE

Although both domestic and export demand for coke receded in 1938, production increased from 1,306,600 short tons in 1937 to 1,602,200 in 1938 with a resultant increase in stocks of almost 100 percent—from 378,600 tons at the end of 1937 to 707,500 at the end of 1938. Domestic demand, which was 1,153,100 tons in 1937, dropped to 1,117,700 tons in 1938, and exports declined from 164,300 tons in 1937 to 155,600 in 1938.

## ASPHALT AND ROAD OIL

Asphalt statistics represent one of the few branches of the oil industry that improved in 1938 over 1937. Domestic demand increased from 3,977,400 short tons to 4,460,600 in 1938. Exports increased from 45,500 tons in 1937 to 50,200 in 1938, but imports at 33,200 tons were slightly lower than in 1937. The increase of 210,400 tons in production—from 4,182,000 in 1937 to 4,392,400 in 1938—was insufficient to meet the increased demand, resulting in reducing stocks from 566,100 tons at the end of 1937 to 480,900 at the end of 1938.

Domestic demand for road oil fell from 7,954,000 barrels in 1937 to 7,775,000 in 1938. Stocks increased from 667,000 barrels at the end

Digitized by Google

of 1937 to 680,000 at the end of 1938, and production declined from 8,087,000 barrels in 1937 to 7,788,000 in 1938. Detailed statistics on asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

### STILL GAS

The production of still or refinery gas suffered the first significant set-back since separate statistics have been gathered for this product, the output in 1938 totaling 236,943 million cubic feet compared with 241,981 in 1937. At least part of this decline probably can be attributed to the conversion of the gas into gasoline by polymerization and it is reasonable to expect that the amount polymerized should increase in future.

Most of the still gas is employed for refinery fuel; it supplied 47 percent of the total B. t. u. used in refineries in 1937 compared with 34 percent in 1931. The proportion burned as refinery fuel declined from 98 percent in the first half of the decade to 93 percent in 1937, following the growth in sales to utility companies.

As the accompanying table shows, the Texas Gulf Coast district produced the greatest amount of any district, with Indiana-Illinois and East Coast, other districts important in cracking, following in order.

*Production of still gas in the United States, 1936–38, by districts*

### MISCELLANEOUS PRODUCTS

Although the principal products of petroleum have been discussed on the foregoing pages many others are becoming increasingly more important. More than half of the production under this classification in 1937 was made up of liquefied petroleum gas (577,000 barrels), petrolatum (434,000 barrels), and absorption oil (201,000 barrels). Other products include alcohols, beautifiers, medicinal oils, lacquers, solvents, perfumes, glycerine, anaesthetics, plastics, and rubber.

The total demand for miscellaneous products declined from 2,249,000 barrels in 1937 to 1,776,000 in 1938, but exports increased from 101,000 to 112,000 barrels.

## WORLD PRODUCTION [4]

The world production of crude petroleum was 3 percent less in 1938 than in 1937, the first decline since the depression of 1930–32. The general decrease was due primarily to a 5-percent curtailment in the production of the United States through proration, in response to a recession in domestic demand, despite new discoveries and increased export demand. Outside the United States the situation varied from country to country, but the total output of all foreign countries was virtually unchanged. North and South America continued to furnish more than three-fourths of the world total. In Venezuela, Colombia, and Trinidad production increased; but in Peru it declined. In Mexico the sharp drop in petroleum production was due to the dislocation of the export trade following expropriation of 17 foreign-owned oil companies on March 18, 1938. The decrease in the output of Rumania may be ascribed to the progressive decline of certain older fields and comparatively little prospecting, in spite of the discovery of new horizons in the Baicoi-Liliesti-Tzintea field. In the Near East a slight decrease in the output of Iran was counterbalanced

[4] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

Digitized by Google

by small increases in the production of Iraq and Bahrein Island and new discoveries in Kuwait and Saudi Arabia. In the Far East, the production of Netherland India, of Sarawak and Brunei, and of Sakhalin increased. On the other hand, the production of British India and Burma declined from 1937 to 1938.

Determined efforts were made in countries of expanding domestic demand and insufficient domestic supply to expand their domestic production of crude petroleum. The U. S. S. R. increased its production of crude petroleum 4 percent from 1937 to 1938 but fell 13 percent below the quotas prescribed by the Five-Year Plan. Virtually all this output was consumed within the Soviet Union; less than 4 percent was exported during 1938. Germany increased its production more than one-fourth, not only by augmenting the output of the older fields but by discovering new fields and acquiring three new fields through the annexation of Austria. In Canada new discoveries in the Turner Valley field more than doubled the output of the Dominion in 1938 over 1937. In Argentina intensified drilling by the Government enterprise compensated for a decline in the output of private companies. Efforts to increase output in Poland and in Japan resulted only in unimportant increases.

*Crude petroleum produced in principal countries of the world, 1934–38, in thousands of barrels*

## UNITED STATES TRADE [5]

*Imports.*—In keeping with the reduction in the domestic output of crude petroleum, total imports of mineral oils, crude and refined, into continental United States were 5 percent less in 1938 than in 1937. They constituted 4 percent of the total new supply of mineral oils both in 1937 and in 1938.

Receipts of foreign crude petroleum decreased 5 percent from 1937 to 1938. Venezuela was the principal source of these receipts, supplying 85 percent of the total imports in 1937 and 90 percent in 1938. Ninety-three percent of the total imports of crude were received at Atlantic coast ports in 1937 and 92 percent in 1938 and the remainder at Gulf coast ports.

Receipts of foreign refined and semirefined oils likewise declined. Imports of fuel oils into continental United States, chiefly in bond for supplies of vessels, were 5 percent less in 1938 than in 1937. Imports of unfinished oils for further refining, both dutiable and in bond, decreased 8 percent from 1937 to 1938. Of the total imports of 25,313,000 barrels of fuel oil and topped petroleum reported for 1938 by the Bureau of Foreign and Domestic Commerce, the Netherland West Indies furnished 24,919,000, Mexico 349,000, and Canada 45,000 barrels.

*Exports.*—In spite of these imports the United States continued to be a petroleum-exporting country. Net exports of crude petroleum increased 28 percent—from 39,921,000 barrels in 1937 to 51,222,000 in 1938. Net outward shipments of refined products from continental United States increased 17 percent—from 75,927,000 barrels in 1937 to 88,619,000 in 1938. Exports and Territorial shipments constituted 13 percent of the total demand in 1937 and 15 percent in 1938. Although imports consisted almost entirely of crude petroleum, bunker oil, and semirefined oils for further processing, obtained from neighboring countries of North and South America, exports and Territorial shipments included not only crude petroleum but a wide variety of finished products shipped to all parts of the earth.

Exports of crude petroleum were 15 percent greater in 1938 than in 1937. More United States crude was purchased by France, Japan, Italy, and Sweden, countries in which the domestic refining of crude petroleum is encouraged by Government policy. On the other hand, Canada, the principal foreign purchaser of United States crude, took 12 percent less crude from the United States in 1938 than in 1937. Increased production of high-grade petroleum in Alberta and larger imports from Colombia were responsible for this decline. The United Kingdom likewise decreased its purchases of crude from the United States, as well as from Peru and Mexico, but took more from the Netherland West Indies, Venezuela, and Iraq. Sales of crude petroleum to Czechoslovakia, Germany, and Brazil were also less in 1938 than in 1937. Virtually no crude petroleum was shipped to the noncontiguous Territories in 1938, although 103,000 barrels were shipped to Hawaii in 1937.

Europe was still the principal external market for American refined oils, taking 40 percent of the motor fuel, kerosene, gas oil and fuel oil, and lubricating oils shipped from continental United States in 1937 and 47 percent in 1938. In spite of increased production of crude petroleum, of the intensive cultivation of substitute motor fuels, and of determined efforts to stimulate the refining of petroleum, Europe remains the major importing area for refined oils in international trade. Although the Netherland West Indies, Rumania, Iran, and Netherland India are rival sources of supply, the United States continued to supply in 1938 about one-sixth of the growing European requirements for refined mineral oils and about one-fourth of the European requirements if the exports of crude petroleum to be processed in European refineries are included.

Exports and Territorial shipments of motor fuel (including refinery gasoline, natural gasoline, naphthas and solvents, and benzol) showed the largest proportional increase of all forms of petroleum shipped from continental United States—a 31 percent advance in 1938 from 1937. The principal increases were in exports to northern and western Europe and to the Netherland West Indies, presumably for reshipment to Europe. Exports to Canada likewise increased considerably. The only noteworthy decrease was in exports to Africa. As in 1937, Soviet Asia found it more convenient to purchase gasoline from the Pacific coast of the United States than to receive shipments from Batum.

As in 1937, refineries of the Texas and Louisiana Gulf coast and of California furnished nearly seven-eighths of the exports and Territorial shipments of motor fuel.

Although the United Kingdom, Sweden, Denmark, and Canada increased their purchases of American kerosene in 1938, the failure of China, Hong Kong, Kwantung, Japan, and the Netherlands to take their customary quantities of lamp oil from the United States led to a decline of 16 percent in shipments of kerosene from continental United States from 1937 to 1938. Kerosene sales to South America, to Africa, and to Australia were also appreciably less in 1938 than in 1937.

A decrease of 2.5 percent in exports of gas oil and distillate fuel oils (from 29,011,000 barrels in 1937 to 28,296,000 in 1938) was more than counterbalanced by an increase of 21 percent in exports of residual fuel oils (from 12,810,000 barrels in 1937 to 15,546,000 in 1938). However, gas oil and distillate fuel oils made up 69 percent of the exports of this group in 1937 and 65 percent in 1938. Large increases in exports of gas oil and distillate fuel oils to the United Kingdom and to Germany did not fully suffice to offset the general decline in similar exports to Europe, the Far East (except for the Philippine Islands), and Latin America (except Mexico). Increased exports of residual fuel oils to Cuba, to Italy, to the Netherlands, to Spain, and to the United Kingdom, as well as to the Philippine Islands, Panama, and Canada, were more than enough to offset declines in exports to Japan, the Canary Islands, Belgium, Mexico, and Greece.

The decline in exports of lubricating oils was general but was greatest in shipments to Europe and to Asia, the two major foreign markets. Decreased sales to the United Kingdom and to the Far East outweighed increased sales to Canada, France, Spain, and smaller foreign consumers.

Shipments of wax from continental United States were 13 percent less in 1938 than in 1937. The largest losses were in sales to Germany, the United Kingdom, Scandinavia, China, and the Union of South Africa. Nevertheless, more wax was sold to Canada, Mexico, Chile, Colombia, Belgium, and Spain in 1938 than in 1937.

*Intercoastal shipments.*—The 9-percent reduction in runs to stills in East Coast refineries was complemented by a 12-percent decrease in their receipts of crude petroleum by tanker from Gulf coast ports from 1937 to 1938. These receipts were equivalent to 86 percent of the total crude petroleum run to stills in East Coast refineries in 1937 and 83 percent in 1938. Receipts of all types of refined products on the East coast from Gulf coast ports increased 3 percent from 1937 to 1938.

Shipments of mineral oils from California to Atlantic ports of the United States by way of the Panama Canal decreased 9 percent from 1937 to 1938. The only increases in these shipments were in crude petroleum and in residual fuel oils. Nevertheless shipments from California made only an insignificant contribution to the mineral oils, crude and refined, available for consumption in the East Coast area.

| Mixed gas | 1046 |
| Interstate movements | 1046 |
| Pipe-line developments | 1050 |

The natural-gas industry experienced a moderate shrinkage in demand in 1938 after 4 years of rapid recovery from the depression low of 1933. Total marketed production had increased 55 percent, from 1,555,000,000,000 cubic feet in 1933 to 2,408,000,000,000 in 1937. However, because of generally adverse business conditions in 1938, marketed production is estimated to have declined to 2,263,000,000,000 cubic feet, or 6 percent below 1937.

Capital expenditures in the production and transportation branches of the industry were much lower than in 1937, as existing facilities were generally adequate for the requirements of current markets. Since the period, 1928–32, when many long-distance gas lines were constructed, managements have emphasized expanding the volume to utilize excess capacity and improving load factors, but at profitable rates. There appear to have been two restraining influences in the last 2 or 3 years upon the extension of pipe lines to new markets. One is the activity in many localities of groups sponsoring competing fuels. The other is the stagnation of capital markets for durable goods, which has almost eliminated public financing as a means of raising money for new gas enterprises.

Estimated consumption of natural gas in the United States was 2,261,285,000,000 cubic feet in 1938, a decrease of 6 percent from the 1937 total of 2,403,041,000,000 cubic feet. The average value at points of consumption is estimated to have increased in 1938 to about 22.1 cents per thousand cubic feet from 22.0 cents in 1937, owing to gains in domestic and commercial values that more than balanced a decline in the average value of gas used for all industrial purposes. In recent years domestic and commercial demand has grown more in States where average sales values exceed the national average than it has in States with below-average rates. This trend is due to the development of important new markets remote from major gas-producing areas and has caused the average value of gas used by these groups of

[1] Data for 1938 are prelimary; detailed statistics with final revisions will be released later.

Digitized by Google

consumers to be sustained in spite of generally declining rates in nearly all consuming areas. The total value at points of consumption of natural gas used in the United States dropped 5 percent in 1938 to about $500,000,000 from $527,529,000 in 1937.

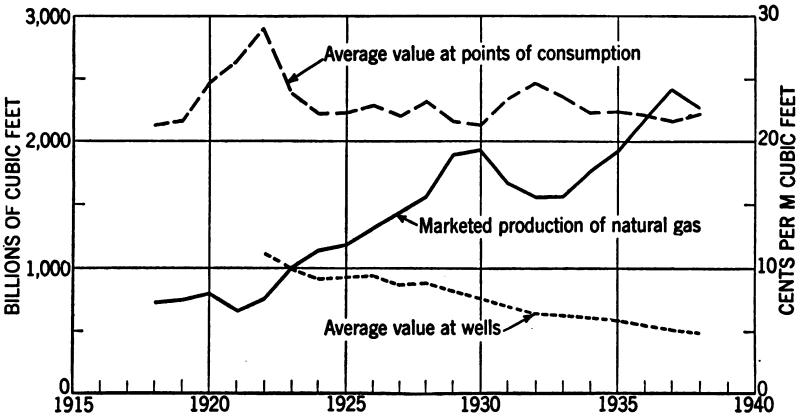

FIGURE 1.—Production and value of natural gas, 1918-38.

As shown in figure 1, the average value of natural gas at the wells is estimated to have decreased from 5.1 cents per thousand cubic feet in 1937 to 4.9 cents in 1938 and the total value from $123,457,000 to about $111,000,000, or 10 percent.

| Percent of total consumption | 100 | [7] 101 | 95 | 84 | 88 | 94 |

[4] Figures not yet available.
[5] Exclusive of oil- and gas-field operators.
[6] Revised figures.
[7] Exceeds 100 percent, as part of the natural gas treated for natural gasoline is blown to the air and not included in total consumption.

Exports of natural gas to Mexico reached a peak of 7,350,000,000 cubic feet in 1936 but declined sharply to an estimated total of 2,000,000,000 in 1938. The Mexican Government requires the use of increasing percentages of gas produced in Mexico, when available, hence production developed south of the Rio Grande River has been replacing large quantities of gas formerly produced in Texas and piped across the international boundary. Exports to Canada of natural gas (mixed with manufactured gas) rose 15 percent in 1938 to 90,000,000 cubic feet; imports from Canada, which come from a single well on the Imperial dome north of Montana, increased to about 375,000,000 cubic feet in 1938 from 289,000,000 in 1937.

## LEGISLATION

A Federal law to regulate interstate transportation of natural gas was passed by Congress and approved on June 21, 1938. It marks the entrance of the Federal Government into the field of gas distribution as a supervisory agency. The Federal Power Commission has the responsibility of administering the act, whose purpose is to supplement the regulatory functions of State and municipal authorities. Heretofore, geographical boundaries have limited the regulatory powers of State and local governments.

The law provides for determination and enforcement of "fair" charges by the pipe-line companies for interstate transportation of natural gas and of reasonable wholesale rates for the sale of gas at "city gates." The Commission also has power to control the construction and abandonment of all interstate gas lines, to prescribe uniform systems of accounts, and to license private parties to export gas to foreign countries.

Digitized by Google

Several important cases are now pending before the Commission relevant to its jurisdiction over construction of new gas lines and rates.

## EMPLOYMENT AND PRODUCTIVITY

The following table is not comparable with a similar table published in the Minerals Yearbook 1938, page 910. Labor employed is expressed in man-hours rather than in number of wage earners. This method affords a more accurate measure of labor effort, because many of the men who operate gas wells work on a part-time basis. In the former table natural-gas production represented the gas marketed from both gas and oil wells. Information is now available on which an approximate separation of the two types of production can be made. Therefore the current table includes the gas produced from gas wells only, from which the relationship between the volume of output and the amount of labor required at gas wells is obtained directly.

*Employment at gas wells, natural gas produced from gas wells, and average output per man-hour in the United States, 1936–37, by States*

| State | Average number of workers | | Total man-hours (thousands) | | "Dry"-gas production (millions of cubic feet) | | Labor productivity (thousands of cubic feet per man-hour) | |
|---|---|---|---|---|---|---|---|---|
| | 1936 | 1937 | 1936 | 1937 | 1936 | 1937 | 1936 | 1937 |
| Arkansas | 37 | 35 | 82 | 73 | 3,950 | 5,700 | 48.2 | 78.1 |
| California | 9 | 18 | 18 | 36 | 8,000 | 14,000 | 444.4 | 388.9 |
| Colorado | 7 | 9 | 16 | 19 | 3,600 | 3,050 | 225.0 | 160.5 |
| Illinois | 6 | 9 | 11 | 15 | 40 | 30 | 3.6 | 2.0 |

[1] Mississippi, Missouri, South Dakota, Tennessee, Utah, and Washington.

Employment at gas wells in the older developed areas is stable under ordinary conditions. Total employment (man-hours) was 7 percent greater in 1937 than in 1936, but most of the gain occurred in West Virginia and Kansas where many new gas wells were drilled and connected to pipe lines. Employment in "dry"-gas fields in California, although small, increased 100 percent in 1937 over 1936 as a result of the growing volume of production from several recently developed fields.

Digitized by Google

It will be noted that the productivity of labor varies widely in different producing States. From a long-term standpoint the controlling factor in cost of labor per unit volume produced is the character of the production. Of course, changes in labor productivity in successive years are influenced by many variable factors, chief among which is probably the current demand for gas. Significant trends in labor productivity cannot be inferred from the data presented until such figures are available for a period of several years.

## GROSS PRODUCTION

The estimates of gross production of natural gas in 1936 and 1937, shown in the following table, have been compiled in a manner similar to those for 1935 published in the Minerals Yearbook, 1937, page 1060. The total production shown for each State is the sum of the quantities of gas marketed for domestic, commercial, and industrial uses plus gas reported as used in oil-field repressuring operations, stored in natural underground reservoirs, and estimated quantities lost or wasted except waste at wellheads.

The output of gas from oil wells has increased rapidly in Kansas, Louisiana, New Mexico, and Oklahoma in recent years. Such production was about 278 billion cubic feet in 1935 and 493 billion in 1937, an increase of 77 percent. In the same period estimated losses and wastage increased nearly 300 percent, or from 51 to 202 billion cubic feet. In Texas, although casinghead-gas production increased moderately, total waste declined because of restrictions placed upon "stripper" operations.

Reports of gas used for repressuring are incomplete in some States, but a trend toward the utilization of more gas for this purpose is evident in most active areas. The total volume increased about 16 percent in 1937 over 1936. Montana and New Mexico were added to the list of States reporting repressuring operations, and increases were indicated in eight other States, Texas, Oklahoma, and Louisiana being the most conspicuous.

The storage of gas in old reservoirs for future use is a minor factor in gas distribution. However, in Kansas and Ohio it is being done on a rather large scale. Gas companies are not often so situated as to profit by this practice, as many variable aspects of supply and demand must be favorable. Therefore it does not seem to offer great promise as a conservation measure.

Part of the increased loss and waste cited above was due to greater shrinkage at gasoline-extraction plants and to more complete reporting of waste in later years. However, it is clear that even with the pronounced improvement in operating technique the exploitation of oil deposits is still wasteful of gas. If the loss in volume incident to removal of natural gasoline is excluded probably more than 80 percent of the total waste of gas in the United States is due to inefficient practices in oil production.

[1] Marketed production plus quantities used in repressuring, stored in the ground, lost in handling, and blown to the air.

[2] Includes gas blown to the air, shrinkage at natural-gasoline plants, and transportation losses but does not include wastage at wellheads.

[3] Produced approximately as follows: 953 million cubic feet in Texas, 746 million in Oklahoma, 401 million in Kansas.

[4] South Dakota, Tennessee, Utah, and Washington.

[5] Produced approximately as follows: 2,071 million cubic feet in Texas, 2,254 million in Oklahoma, 1,033 million in Kansas.

[6] Produced approximately as follows: 2,951 million cubic feet in West Virginia, 531 million in Kentucky, 1,528 million in Ohio.

## MARKETED PRODUCTION

The 6-percent decline in total marketed production in 1938 (to 2,263,000 million cubic feet from 2,407,620 million in 1937) was caused chiefly by smaller demand for most industrial uses. Output declined in all States except New York, Illinois, and New Mexico in 1938. In 1937 marketed production reached an all-time peak in Kansas, Kentucky, Louisiana, Michigan, Mississippi, Montana, New Mexico, New York, and Texas.

The volume marketed from Texas fields in 1938 almost equaled that in 1937. In contrast, output declined materially in other leading producing States. Texas production has grown from 31 percent of the national total in 1933 to 37 percent in 1938. Total marketed production of the five leading States represented 82 percent of the United States total in 1933 and 81 percent in 1938.

The average value of gas at the wells increased in 1937 over 1936 in seven States, notably Louisiana, Michigan, and Wyoming. It declined substantially in Missouri, New York, Pennsylvania, and West Virginia.

*Natural gas produced in the United States and delivered to consumers, 1933–37, by States, in millions of cubic feet*

| Year | Arkansas | California | Colorado | Illinois | Indiana | Kansas | Kentucky | Louisiana | Michigan | Mississippi | Montana | New Mexico |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1933 | 8,288 | 259,799 | 2,449 | 1,631 | 1,544 | 41,596 | 31,380 | 197,826 | 1,528 | 8,679 | 14,391 | 19,148 |

## WELLS

Development was curtailed in most active sectors in 1938, total gas completions being 2,236, about 21 percent less than in 1937. The influence of slightly reduced market requirements and the existence in many important fields of developed capacity in excess of current requirements of the pipe lines lessened materially the need for new wells. Therefore, a large percentage of the gas completions during 1938 were drilled because of lease obligations or in connection with oil exploration. Active exploitation proceeded in a few highly competitive flush areas, such as the Oriskany fields near Charleston, W. Va.; Allegany and Steuben Counties, N. Y.; and the smaller new fields in Lawrence County, Ill., and Jackson County, Mo.

Digitized by Google

In Illinois, Indiana, Mississippi, Missouri, Oklahoma, and Wyoming the number of gas completions was somewhat larger in 1938 than in 1937. Declines were general elsewhere; the most conspicuous were in Kansas, Kentucky, Michigan, Texas, and West Virginia.

As shown in the accompanying table the number of gas wells producing as of December 31, 1937, was 55,370 compared with 54,500 a year earlier. Subtraction of the net increase of 870 producing wells from the 2,834 wells drilled during 1937 indicates that 1,964 gas wells were abandoned in that year.

The number of producing gas wells in Texas at the close of 1936 and 1937 has been adjusted to conform to records of the Railroad Commission of Texas.

## REVIEW OF FIELD DEVELOPMENTS, BY STATES

*Arkansas.*—Gross production of natural gas in Arkansas increased 65 percent to 20,557 million cubic feet in 1938 compared with 12,485 million cubic feet in 1937, according to information received from George C. Branner, State geologist.

The principal increase was in Miller County, where gas production totaled 11.1 billion cubic feet in 1938 and only 1.4 billion in 1937. Most of the Miller County gas came from new oil wells with high gas-oil ratios in the Rodessa extension. Gas output was larger in 1938 than in 1937 in Union, Sebastian, Pope, and Nevada Counties but declined substantially in Crawford, Johnson, Ouachita, and Franklin Counties. Columbia and Lafayette were added to the list of counties reporting production of natural gas in 1938.

Only three gas-well completions were reported in 1938. The No. 1 Bryan & Khilling (sec. 22, T. 8 N., R. 29 W.), in Franklin County

Digitized by Google

made 1.9 million cubic feet per day from 2,600 feet. In Johnson County the No. 2 Hudson (sec. 14, T. 10 N., R. 24 W.) was completed with an initial capacity of 40 million cubic feet per day and rock pressure of 1,300 pounds from a depth of 3,401 feet. The No. 1 Raulston (sec. 12, T. 17 S., R. 14 W.), Union County, was completed with a capacity of 1.5 million cubic feet per day from 3,184 feet and a rock pressure of 1,100 pounds. In Miller County the No. B–2 Thomas (sec. 12, T. 20 S., R. 28 W.) made 12 million cubic feet per day of gas and 50 barrels of oil. Forty other completions in Miller County increased considerably the available reserves of casinghead gas. Three oil discoveries in Columbia County also added to current supplies of casinghead gas.

Gas pipe-line construction in Arkansas in 1938 was limited to one 6-inch line running from the Schuler field, Union County, to El Dorado, a distance of 18 miles.

*California.*—Although the marketed production of natural gas in California is estimated to have declined 4 percent in 1938 from 1937, gross production probably increased from 357 billion cubic feet in 1937 to 365 billion in 1938. Total gas processed for natural-gasoline extraction increased about 2 percent to 388 billion cubic feet, including 60 billion or more "recycled" back to the oil sands.

Production from "dry" gas fields, which represents only a small fraction of the total gas production in California, was probably somewhat larger in 1938 than in 1937. Gas wells often are shut in during the summer and allowed to produce into the pipe lines during the winter when demand for gas expands.

Drilling in the gas fields is retarded at present by the fact that productive capacity is larger than immediate needs for gas. Nine wells were completed in old fields in 1938 and 16 in 1937. The only active development was in the Rio Vista gas field, where eight of the completions were reported, extending the proved area eastward from Solano into Sacramento County. The other gas well was drilled at McDonald Island and increased the number of producers in that field to seven.

In addition, two gas discoveries were made in 1938. In Willow district, Glenn County, more than 100 miles north of San Francisco, a gas blow-out occurred at the Williard No. 1 on January 8, 1938. The reported flow of 75 million cubic feet per day wrecked the rig. A second well was drilled to 6,014 feet and, when plugged back to 2,364 feet, made 6 million cubic feet of gas. The value of the discovery is still in doubt.

The Potrero Hills No. 1, a wildcat in Solano County, was completed in December 1938 for 5 million cubic feet of gas from a depth of 3,238 feet, apparently opening up a new area for gas production.

Several oil discoveries were made in 1938 which indicated large additions to the available reserves of casinghead gas. Among these were Southeast Coalinga in Fresno County; Tupman, Coles Levee, Wasco, and Greeley (deep zone) in Kern County; and Montebello (deep zone), Wilmington, and Long Beach in Los Angeles County.

Development of gas production in recent years in the regions east and north of San Francisco Bay is providing supplies of natural gas for new market areas in the northern part of the State that hitherto have been inaccessible to natural-gas service.

Gas pipe-line construction was very small. An 8-inch line 14 miles long was built from Merced, Merced County, through Atwater to

Digitized by Google

Livingston. In the Montebello oil field 10 miles of 10-inch line were laid to carry casinghead gas.

*Colorado.*—The only changes in the natural-gas industry in Colorado during 1938 were in rates of production from the various fields, which generally decreased. The following data have been supplied by H. J. Duncan, supervisor, Geological Survey, Casper, Wyo.

Total gas production was 1,487 million cubic feet, a decline of 45 percent from 1937. Output of the Hiawatha field (Colorado portion), the principal gas source within the State, was 1,301 million cubic feet, almost 50 percent less than in 1937. The Garcia field with 54 million cubic feet and the Craig field with 4 million cubic feet also produced substantially less gas in 1938. Small increases were recorded from the Thornburg and Berthoud fields, which produced 72 and 55 million cubic feet, respectively, of the total marketed output in 1938.

Gas from the Hiawatha field is consumed in Salt Lake City, Utah, and that from the other producing fields is utilized in Colorado for domestic and commercial purposes.

Waste of gas from gas fields was very small. Approximately 14 million cubic feet of gas were blown to the air from the recently discovered Wilson Creek oil field. The Garmesa, Piceance Creek, Powder Wash, and White River fields remained shut in for lack of a market.

*Illinois.*—The most important natural-gas development in Illinois in 1938 was the discovery of a large volume of gas in Lawrence County. Information is taken from a report by Alfred H. Bell and George V. Cohee, Illinois State Geological Survey.

Two small gas wells were drilled in 1937 in sec. 30, T. 5 N., R. 10 W., Lawrence County, producing from a Pennsylvanian sand at about 620 feet. In July 1938 the Scott Gray No. 1 (sec. 13, T. 4 N., R. 11 W.) obtained gas in the Buchanan sandstone at a depth of 1,061 feet and was completed with an initial capacity of 16 million cubic feet per day. Thirteen producing wells were drilled in the field in 1938 with an average capacity of 14 million cubic feet per well. The proved area in both fields was about 500 acres at the end of the year. Deeper potential oil- and gas-producing formations have not yet been tested. The heating value of the gas is about 950 B. t. u. per cubic foot. It comprises methane with minor amounts of ethane, carbon dioxide, and nitrogen.

The Ayers gas field in Bond County produced 23.2 million cubic feet of gas in 1938, which brought its cumulative production to 167 million cubic feet from a productive area of 325 acres. Of the 19 wells drilled in the field, 10 are still producing. The heating value of the gas is 1,050 B. t. u. per cubic foot.

A small quantity of natural gas is being produced with oil in many of the new oil fields in Illinois. Some gas is being returned to the producing sands in the Louden (Beecher City) field, and a similar project has been started in the Salem (Lake Centralia) field. Gas is used in field operations, and some is processed for extraction of natural gasoline. The excess gas is burned in flares.

A 3-inch pipe line which had been built in 1937 from sec. 30, T. 5 N., R. 10 W., Lawrence County, to Oaktown, Ind., was replaced in 1938 with a 6-inch line, and two 4-inch gathering lines were laid to the Buchanan sand field a short distance southwest.

Digitized by Google

*Indiana.*—Gas-well completions in Indiana in 1938 numbered 41 compared with 34 in 1937. Exploration for gas and oil was stimulated by the successful operations in Illinois, and an active leasing campaign was started in southwestern Indiana.

Two gas discoveries were reported, the No. 1 Ogle (sec. 35, T. 8 N., R. 10 W.), Sullivan County, being the more important. This well made 2 million cubic feet of gas per day from a stray sand in the Pennsylvanian series at a depth of 821 feet. The other discovery was the No. 1 Bobrink (sec. 15., T. 6 N., R. 1 W.), Dearborn County, which was completed at a depth of 450 feet with an initial capacity of 300,000 cubic feet of gas per day. The Oaktown field in Knox County was extended during 1938 by completion of new wells producing from Pennsylvanian sands.

Indiana produced 1,551 million cubic feet of natural gas in 1937 and probably a larger quantity in 1938.

A new 6-inch line was laid in 1938 to bring gas from recently developed gas fields in Lawrence County, Ill., to supplement the supply of a line in the Oaktown field.

*Kansas.*—Compared with 1937 there was a considerable decrease in 1938 both in total number of gas wells drilled and new pools opened in Kansas, according to a report by Raymond P. Keroher, geologist, Kansas Geological Survey. In western Kansas, 75 gas wells were completed, 25 of which also produced oil in commercial quantities. Only one of these was a discovery well. In eastern Kansas only four gas wells were reported, although many more were drilled.

The single discovery, No. 1 Young (sec. 34, T. 27 S., R. 21 W.), was completed June 13 at 5,037 feet in Mississippi lime, after having been plugged back from 5,930 feet in the Arbuckle. After treatment with 14,000 gallons of acid the well made 6 million cubic feet of gas, 48 barrels of oil, and 200 barrels of water initially. The field opened by this well, which is 50 miles from the nearest commercial oil production and the only one in Ford County, was officially named the Pleasant Valley field.

The greatest gas activity in western Kansas in 1938 was in Barber, Grant, Kearney, Reno, Rice, Stafford, and Stevens Counties. Fewer gas wells were drilled in Ellsworth, Harvey, Kingman, McPherson, Pratt, and Russell Counties.

Eight wells were added to the Medicine Lodge gas field in T. 33 S., R. 13 W., Barber County, during 1938. Their average potential was 11 million cubic feet from the Mississippi lime at depths of 4,630 to 5,045 feet.

The Hugoton field of Grant and Stevens Counties was again the most active locality in the State. Fifteen wells were completed in Stevens County with an average initial capacity of about 9 million cubic feet of gas per well, and eight were completed in Grant County with an average of 11 million cubic feet. The gas at Hugoton is obtained from rocks of the Chase and Sumner groups of Permian age at depths of about 2,600 to 2,900 feet.

In the Holcomb field (T. 25 S., R. 35 W.), Kearney County, six wells of comparable capacity and depth were completed in the same reservoir formations. Two large gas wells of 65 and 68 million cubic feet capacity were drilled in the Cunningham pool of Pratt and Kingman Counties. Production is from the Viola lime at 3,950 and 4,292 feet.

Digitized by Google

In Reno County, a 1.5-million cubic-foot well was completed in the Lerado field, and two were completed in the Yoder field with total capacity of 17.5 million cubic feet. One gas well and several oil wells with high gas-oil ratios were drilled in the Burrton field.

Four wells were drilled in the Lyons gas field (T. 20 S., R. 8 W.), Rice County, during 1938 with potentials ranging from 10 to 51 million cubic feet per day. One smaller gas well was completed in the Thurber field (T. 21 S., R. 7 W.) and one in the Stumps field (T. 17 and 18 S., R. 10 W.).

In McPherson County one well of 7 million cubic feet capacity was drilled in the Graber pool (T. 21 S., R. 2 W.), and two completions in the Ritz pool (T. 19 S., R. 1 and 2 W.) produced 30 and 29 million cubic feet of gas, respectively, with comparatively little oil.

Wells that produced gas in commercial quantities along with oil were reported as follows: One each in the Hall and Letsch fields of Russell County; one in the Kip field; and eight in the Zenith field of Stafford County. One well in the Sperling pool (T. 22 S., R. 2 W.), Harvey County, was completed in the Hunton lime at a depth of 3,249 feet with an initial production of 24 million cubic feet of gas and 164 barrels of oil.

In eastern Kansas a 5-million cubic-foot well was completed in the Penwest field (T. 31 S., R. 5 E.) and a well of the same size in the Tisdale field (T. 32 S., R. 5 E.), both in Cowley County. An important well was reported in the Andover field (T. 27 S., R. 3 E.), Butler County, with an initial capacity of 13.5 million cubic feet of gas and 204 barrels of oil. No adequate records of eastern Kansas development are compiled, but probably drilling was less active in 1938 than in 1937.

Reconditioning of the Craig-Zarah gas field in Johnson County for use as a storage reservoir was begun early in 1938 and continued most of the year.

*Kentucky.*—Gas development in Kentucky in 1938 was substantially less, but the volume of gas deliveries was approximately the same as in 1937, according to information in a report by C. D. Hunter, geologist, Kentucky West Virginia Gas Co., I. B. Browning, geologist and operator, and Ralph Thomas, geologist, Ashland Oil & Refining Co., all of Ashland, Ky. In eastern Kentucky not over 50 gas wells were completed, a decline of about 50 percent from 1937. Operations were curtailed because of the continued development of large volumes of Oriskany-sand gas in West Virginia and of the already developed producing capacity in eastern Kentucky which exceeds current market requirements. Average initial production of the eastern Kentucky wells was 4 to 5 hundred thousand cubic feet per day.

Gas was used for repressuring the Weir sand fields of Johnson and Magoffin Counties but only in small amounts, owing to the local scarcity of gas. The Flat Gap field, Johnson County, although nearly depleted, furnished some gas for repressuring. In Powell County the Janet field furnished some low-pressure gas to short pipe lines in Lee and Powell Counties for use as fuel and for repressuring. In a small, isolated oil field in Martin County about 150,000 cubic feet per day of casinghead gas was processed for extraction of gasoline, yielding 4 to 5 barrels daily.

In western Kentucky only 41 gas wells were drilled, distributed by counties as follows: Ohio 12, Daviess 6, Breckenridge, Grayson, and

Digitized by Google

Hancock 5 each, Henderson 4, Webster 3, and McLean 1. Total gas completions equaled only about one-third those in 1937. Because of limited marketing facilities in the area only a small part of the gas developed can be sold, hence little effort is directed toward the discovery and development of new gas-producing areas. Most gas-well completions are the result of wells started and drilled in search of oil.

No major gas pipe-line construction was reported during the year.

*Louisiana.*—Gas-well completions in north Louisiana in 1938 declined to 137 compared to 184 in 1937, according to a report by Cyril K. Moresi, State geologist. Of this number, 59 were combination gas and distillate wells and 4 wet gas wells. In addition, the Shreveport field, discovered in July 1938, had 6 completions which produced large volumes of gas with oil from the basal Glen Rose horizon at depths of 5,500 to 5,600 feet.

The Cotton Valley field, Webster Parish, was the most active area with 59 completions, all of which were combination wells. Eighteen gas wells were drilled in the Rodessa field, Caddo Parish, in 1938, a 51-percent decline from 1937. Total open-flow capacity of the 1938 completions was 358 million cubic feet per day.

In the Monroe gas field in northeastern Louisiana 53 wells were drilled in 1938 with a total capacity of 302 million cubic feet per day. In 1937, 89 gas wells were drilled in this field. The total number of wells capable of producing gas increased during 1938 from 1,136 to 1,182. Their open-flow capacity, however, decreased from 4,648 million to 4,310 million cubic feet per day. Of the other gas fields in northeastern Louisiana, the Richland had 75 gas wells with a total capacity of 230 million cubic feet at the end of the year, Epps had 4 wells with 107 million, and Simsboro had 3 wells with 133 million.

Other gas completions were scattered in four fields in Caddo Parish, one each in De Soto, Webster, and Bienville Parishes.

Distillate was discovered in the old Shongaloo oil and gas field, Webster Parish, in June 1938. The discovery well made 2.7 million cubic feet of gas with 279 barrels of distillate from the Cotton Valley formation at 9,010 feet. Spacing of 160 acres per well has been prescribed for future developments. The Logansport field in De Soto Parish was discovered by the Parker No. 1 in June 1938. The well produced 4.3 million cubic feet of gas with 14 barrels of distillate from the Glen Rose formation at 5,187 feet.

Proration schedules of allowable gas production are in force in the Cotton Valley, Rodessa, and Shreveport fields.

Gross production from gas wells in the State in 1938 was 260 billion cubic feet, 14 percent less than in 1937. Of the total, about 7 billion cubic feet came from southern Louisiana fields and the rest from northern fields. Production from the northeastern Louisiana fields—Monroe, Richland, and Epps—declined 18 percent in 1938 to 179 billion cubic feet. Withdrawals from Rodessa gas wells dropped in 1938 to 26.5 billion cubic feet from 56.3 billion in 1937. Cotton Valley production rose sharply from 10.4 billion cubic feet in 1937 to 20 billion in 1938.

An increase of almost 100 percent was reported in casinghead-gas production. The total was 100.8 billion cubic feet in 1938 compared with 55.8 billion in 1937. The output of northern Louisiana fields rose from 17.3 to 43.4 billion cubic feet and that of the coastal fields from 38.5 to 57.1 billions. The Rodessa field produced 34.6 billion

Digitized by Google

in 1938 and only 14.3 billion in 1937. The radical changes in volume of production reported from gas wells and oil wells at Rodessa appears to be due largely to reclassification of wells. Gas production from the field totaled 70.6 billion cubic feet in 1937 and 61.2 billion in 1938. Of the northern fields, Lisbon, Cotton Valley, and Sligo were credited with substantial increases in output of casinghead gas.

Casinghead-gas production was reported from 70 coastal Louisiana fields in 1938 and 43 in 1937. Part of the indicated increase in production in 1938 is accounted for by more complete reports than previously. The most important fields in 1938, in order of output, were Tepetate, 9.5 billion cubic feet; Roanoke, 7.1; Lafitte, 6.3; English Bayou, 5.4; Iowa, 5.0; Bosco, 3.5; and Jennings, 3.0. Roanoke production increased from 132 million cubic feet in 1937 to 7,108 million cubic feet in 1938. Important increases in output also were made at English Bayou, Jennings, Lafitte, Lake Long, and Ville Platte fields.

*Michigan.*—Reported gas production in 1938 was 9,233 million cubic feet, about 1 percent less than in 1937, according to F. R. Frye, petroleum engineer, Michigan Department of Conservation. This total includes 1,515 million cubic feet of casinghead gas, a gain of 84 million cubic feet over 1937.

Only 27 gas wells were drilled during 1938, in contrast to 66 in 1937 and 206 in 1936, and 21 were abandoned, leaving a total of 441 producing on January 1, 1939, a net increase of 6 for the year.

New producing areas were developed in Winfield (T. 12 N., R. 9 W.) and Home Townships (T. 12 N., R. 6 W.), of Montcalm County, and Grant (T. 17 N., R. 4 W.), Lincoln (T. 18 N., R. 5 W.), and Freeman Townships (T. 18 N., R. 6 W.), of Clare County. Most of these fields were connected to existing pipe lines.

Perhaps the most interesting gas discovery was in a well drilled in sec. 32, T. 23 N., R. 5 W., Enterprise Township, Missaukee County. This well encountered about 3.7 million cubic feet of gas in the Michigan Stray sand at 1,000 to 1,008 feet. The discovery is about 30 miles from the nearest production in this sand and adds a large area of possible gas-producing territory to that already known. The gas was cemented off and the well drilled deeper.

*Mississippi.*—Natural-gas production in Mississippi, as reported by H. M. Morse, State oil and gas supervisor, was 14,298 million cubic feet in 1938, a slight gain over that of 1937, the previous peak year. The Jackson field supplied the entire gas output of the State in 1938, as the depleted Amory field of Monroe County did not produce after 1937.

Salt-water encroachment in the Jackson field has become a serious problem, as indicated by the sharp reduction in the number of producing gas wells from 90 on January 1, 1938, to 59 at the end of the year. Six gas wells and one dry hole were drilled in the field during 1938.

In August 1938 one of the wells caught fire and caused an estimated waste of 300 million cubic feet of gas. A temporary tax of 7.5 percent of the output was placed upon all wells to reimburse the State for money expended to extinguish the fire. General waste of gas approximated 50 million cubic feet, making a total of 350 million cubic feet of gas wasted in 1938.

Digitized by Google

The gas produced in Mississippi and sold to pipe lines was consumed approximately as follows: 25 percent for domestic purposes, 15 percent commercial, and 60 percent industrial. Over 40 percent of the State production, or 6,340 million cubic feet, was marketed through pipe lines in Alabama (28 percent), Florida (13 percent), and Louisiana (3 percent).

Nine wildcat wells were drilled in Mississippi in 1938, all of which were unproductive.

*Missouri.*—Drilling in Missouri increased sharply in 1938, according to a report by Frank C. Greene, geologist, Missouri Geological Survey. Of 60 gas wells completed, 56 with a total initial open-flow capacity of 52 million cubic feet were in Jackson County and 4 with 0.5 million cubic feet total capacity were in Cass County.

The most active area was the so-called Bartlesville or Sniabar "shoestring" sand field in Jackson County which was extended southeastward. It seems probable that the producing sand is at the horizon of the Burbank sand.

A new Squirrel sand gas pool was developed in secs. 30 and 31, T. 49 N., R. 32 W., Jackson County. A pipe line to take gas from this pool was completed in March 1939.

Wildcatting in Clay, Hickory, Marion, Platte, and St. Clair Counties was unsuccessful, resulting in 16 dry holes. An active leasing campaign was carried on in the "Forrest City Basin" of northern Missouri preparatory to drilling in search of new oil and gas fields.

*Montana.*—Drilling and production of natural gas in Montana proceeded at reduced rates in 1938, according to a report by H. J. Duncan, supervisor, Geological Survey, Casper, Wyo. Twenty-one gas wells were completed in oil fields with a combined open flow of 122 million cubic feet per day. In 1937, 40 wells were drilled with a total capacity of 104 million cubic feet. No construction of gas transmission lines or processing plants was reported. A gas well was completed for a flow of 8 million cubic feet per day in the Moulton sand at 2,572 to 2,585 feet, 4 miles north of the Cut Bank gas area.

Gas withdrawals were 20,463 million cubic feet in 1938, about 14 percent less than in 1937. Mild winter weather and curtailed operations at copper smelters and other industrial plants contributed to the reduction in demand for gas.

Production of gas from the several fields in 1938 is shown in the accompanying table, with data on the principal uses to which it was put. About 60 percent of the total decline in output occurred at Cut Bank, and less drastic reductions were made at the Cedar Creek and Kevin-Sunburst fields. Of the less important producing areas, three (Box Elder, Dry Creek, and Whitlash) showed small increases in output and three (Bowdoin, Bowes, and Hardin) small declines.

Al gas produced, except that from the Cedar Creek field, was consumed within the State. Importations from the Rogers Imperial well in Canada continued to augment the supply for Great Falls. The quantity thus imported was about 375 million cubic feet in 1938.

Wastage of gas from gas fields is very small, being estimated at 75 million cubic feet due to losses in drilling in, testing, and faulty connections. About 10 million cubic feet of gas produced with oil escaped to the atmosphere.

*New Mexico.*—Sales of natural gas from the fields of southeastern New Mexico increased moderately in 1938, and the quantity processed

Digitized by Google

at gasoline extraction plants gained 62 percent over 1937. Data have been furnished by E. A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex.

*Source and distribution of natural gas in Montana in 1938* [1]

| Field | Total production (M cubic feet) | Utilization | | | Location of principal markets |
|---|---|---|---|---|---|
| | | Domestic (M cubic feet) | Industrial | | |
| | | | M cubic feet | Consumer | |
| Bowdoin | 656,661 | 492,496 | 164,165 | Steam boilers | Glasgow, Malta, Fort Peck, etc. |

[1] Data supplied by H. J. Duncan, supervisor, Geological Survey, U. S. Department of the Interior.
[2] To Bozeman, Livingston, Big Timber, and intervening towns, mainly domestic.
[3] Excludes Cedar Creek and Dry Creek.

Domestic and commercial markets absorbed 24,399 million cubic feet, of which 23,700 million were produced in Lea County and the balance in Eddy County. A total of 91,800 million cubic feet was run through gasoline plants in 1938 compared with 56,500 million in 1937. Approximately 2,500 million cubic feet were used in gas-lift operations in oil wells and an additional 2,500 million for general fuel and power purposes in the fields.

Nineteen gas wells were completed in 1938 with total initial capacity of 263 million cubic feet per day; both the number and capacity declined from 1937. However, the average daily capacity per gas well increased in 1938 to 13.8 million cubic feet from 10.5 million in 1937. Most gas completions were in or near proven areas and were incidental to the search for oil. The discovery well in the new Lovington oil field of Lea County was completed as a gas well gaging approximately 4.5 million cubic feet from the Yates anhydrite zone.

Although still relatively small, interest and drilling activity have increased in the areas favorable to carbon dioxide development in the Bueyeros field, Harding County, the Wilcox field, Torrance County, and the Wagon Mound area, Mora County.

Production in northwestern New Mexico in 1938 rose 12 percent over 1937 to 2,272 million cubic feet, as reported by J. A. Frost, district engineer, Geological Survey, Farmington, N. Mex. Withdrawals from the Kutz Canyon field increased 29 percent to 1,516 million cubic feet in 1938. Output of the other two producing fields, Blanco and Ute Dome, declined moderately to 29 million and 728 million cubic feet, respectively. No wells were drilled in the district in 1938. Gas waste was small, being limited to that incidental to blowing wells during normal operations.

About 40 percent of the marketed production was used for domestic purposes and 60 percent for industrial.

159434—39——66

*New York.*—As reported by C. A. Hartnagel, assistant State geologist, drilling for natural gas in 1938 was notably active in the southwestern part of the State, in Steuben and Allegany Counties, where the results of deep exploration in the preceding year or two had uncovered productive pools in the Oriskany sandstone. The gas comes from a depth of 4,000 feet or more and is found along anticlinal structures that extend northeast-southwest and probably are a part of the Appalachian folding. Within the two counties 42 wells were drilled, of which 31 were listed as producers. At the close of the year 15 wells were drilling.

Among the outstanding developments was the discovery in March 1938 of the Beach Hill pool, town of Willing, Allegany County, about 4 miles northeast of the State Line field. The new pool is situated on the Watkins (Smethport) anticline. Eleven wells were completed, of which seven were producers with total initial capacity of 79 million cubic feet per day. The Oriskany sand in this field is reached at depths of 4,740 to 5,000 feet. In the area between the Beach Hill and Greenwood pools two wells were drilled that found gas, but they were soon drowned out by salt water and abandoned.

The Woodhull field of Steuben County, discovered in 1937, continued to give good wells. Eighteen producers were drilled during 1938 with average initial capacity of 6.3 million cubic feet per well, compared with 16.6 million cubic feet per well for 20 wells completed in 1937. Six wells were drilling as the year ended.

In Troupsburg Township three wells were completed, all of which were productive. In Greenwood the only new well had to be abandoned because of salt-water intrusion. The town of West Union had two completions, one dry and the other moderately productive. East of Steuben County in Chemung County, further tests of Oriskany sandstone were conducted during 1938 but were unsuccessful. Exploration was in progress in Cayuga and Oneida Counties of central New York. The shallow Camden field, which produces from the Trenton limestone in northern Oneida County, was developed further with favorable results.

From 1934 to 1937 natural-gas production in New York more than tripled owing to development of the Oriskany sand, currently the principal source of gas in the State.

*Ohio.*—Both gas production and drilling in Ohio declined in 1938, according to a report by Dewitt T. Ring, geologist, Ohio Fuel Gas Co. Gas-well completions decreased 14 percent from 1937 and totaled 433—423 in central and southeast Ohio and the remaining 10 in the Lima field. The average initial capacity was 459,000 cubic feet per well; this slight increase over the 1937 average of 442,000 was due chiefly to development of larger wells in the Clinton sand.

Most of the new production came from extensions to existing productive areas rather than from important discoveries. The most active counties were Washington with 44 gas-well completions, Athens 41, Guernsey 35, Licking 32, Knox 28, Meigs 24, Stark 24, and Noble 22.

The Clinton sand yielded a total initial volume of 138 million cubic feet per day from 134 new gas wells, an average of over 1 million cubic feet per well. Continued development of Clinton sand areas in Tuscarawas County resulted in completion of 15 wells in 1938—3 in Franklin Township, 2 in Sandy, 8 in Lawrence, and 1 each in

Digitized by Google

Dover and Jefferson Townships. These wells ranged in depth from about 4,500 to 4,950 feet and had initial reservoir pressures of approximately 1,200 to 1,400 pounds. Their open-flow capacities ranged from 28,000 to 8,283,000 cubic feet and averaged only 320,000 cubic feet per well.

Five gas wells drilled in the Newburg sand, a dolomitic phase of the lower Niagara formation, had average open-flow capacities of about 1 million cubic feet per well. Two of these, in Mayfield Township, Cuyahoga County, produced 300,000 cubic feet each naturally with rock pressures of 1,120 pounds. Their open flows were increased to 2.2 million and 1.3 million cubic feet by treatment with acid.

The other outstanding sources of gas production continued to be the Berea sand and the shallower sands above it; 150 Berea wells were completed in 1938, with total initial capacity of 21 million cubic feet per day, and 106 shallow-sand wells, with a total capacity of 29 million cubic feet. Wells drilled to other producing horizons had a total open-flow capacity of about 5 million cubic feet and were as follows: Devonian shale 16, lime 13, Austinburg sand 2, Trenton lime 7.

Further prospecting of the Oriskany sand was unsuccessful in 1938. In Ohio the Oriskany is found only in the eastern part of the State, and its distribution is erratic, the formation being absent in large areas. A well in sec. 16, Sutton Township, Meigs County, penetrated less than 8 inches of Oriskany with a slight show of gas at 3,814 feet. An Oriskany test well in Washington Township, Tuscarawas County, had a show of gas and was abandoned at 3,733 feet. At the close of the year an Oriskany test well was drilling on the Miller farm, sec. 23, German Township, Harrison County, and another in West Virginia on the Burning Springs anticline a short distance south of the Ohio River, in Grant district, Pleasants County.

No new gas- or air-repressuring projects were started in 1938. Five are now in operation, and another was scheduled to start in the eastern part of the State early in 1939.

*Oklahoma.*—Gross production of natural gas in Oklahoma in 1938 was approximately 25 percent less than in 1937, according to records of the Oklahoma Tax Commission. The principal causes of the decline were shrinkage in industrial demand and curtailment in the use of high-pressure gas in oil-production operations in the northern part of the Oklahoma City field. The latter activities consumed large volumes of gas in 1937, most of which was dissipated to the air after forcing the oil to the surface at rapid rates. Casinghead gas production was 252 billion cubic feet in 1938, and production from gas wells was 75 billion cubic feet.

The number of gas wells completed in 1938 was about 160 compared with 123 in 1937. They were scattered over 27 counties, the most active being Caddo, Muskogee, Pontotoc, Creek, Okmulgee, Texas, Stevens, and Osage.

An important gas reserve was proved in Texas County where eight gas wells were completed at rather widely separated points. They ranged in capacity from 3 to 37.5 million cubic feet per day each. The development is an extension of the great Hugoton area of southwestern Kansas, which produces from Permian limestone at depths of 2,700 to 2,900 feet.

Digitized by Google

Active drilling in the old Cement field, Caddo County, resulted in completion of several very large gas wells. Capacities of some individual wells were reported as exceeding 100 million cubic feet per day.

The Wolfe gas field (sec. 8 T. 1 N., R. 2 E.), Murray County, was discovered in June 1938, when a well produced 34 million cubic feet of gas from the Bromide at 2,235 to 2,265 feet. Production units of 40 acres were prescribed for the area by the Corporation Commission, which also limited production rates to 25 percent of "potential" open-flow capacities. A show of oil appeared later with the gas. Other gas discoveries were reported in Muskogee, Okmulgee, Payne, Seminole, Kay, Osage, Pittsburg, and Beckham Counties.

Repressuring and maintenance of reservoir pressures in oil sands by injection of natural gas continued to spread in Oklahoma in 1938. About 125 injection wells were drilled in the northeast quarter of the State. Gas is being returned to the oil sands under large unitized blocks of leases in the South Burbank pool and the Avant district, Osage County; the Billings pool, Noble County; and the new Ramsey pool, Payne County.

In December 1938 the Osage Indian Agency notified all operators in the Burbank field that surplus casinghead gas must be returned to the oil sand.

*Pennsylvania.*—Production of natural gas and drilling activity in Pennsylvania declined in 1938, according to information supplied by J. G. Montgomery, Jr., superintendent and chief geologist, United Natural Gas Co., Oil City, Pa.

Completions of new shallow-sand wells during 1938 in the northwest counties declined 30 percent, all areas showing decreases except the new Sliverville sand field southwest of the Bradford oil field. Most wells in this field produced oil as well as gas. No new shallow-sand fields of importance were found.

Two Oriskany-sand discoveries were made, both in Potter County. The first, in Bingham Township, had subnormal rock pressure, indicating that it may be an eastern extension of the older Ellisburg field. The second was in Sharon Township. Developments in 1938 in the four counties in Pennsylvania that produce gas commercially from the Oriskany sand or the Onondaga lime immediately above it resulted in completion of 12 Oriskany gas wells as follows: In Beaver County two producing wells with open-flow capacity of about 3 million cubic feet each and one dry hole were drilled, making a total of five wells producing from the Oriskany sand in this pool at the end of the year. In Fayette County two producers and one dry hole were drilled, making three producing wells in this area. Capacities of gas wells in this area ranged from 2 to 3.5 million cubic feet each with a rock pressure of about 3,000 pounds and depths from 6,825 to 8,159 feet. In Potter County six producers with total capacity of 44.6 million cubic feet per day and nine dry holes were completed. Open-flow tests ranged from 1.9 to 17 million cubic feet per day and rock pressures from 555 to 1,920 pounds. In Tioga County, two producing wells and two dry holes were drilled. Open-flow capacities were 2 and 2.7 million cubic feet and rock pressures 2,090 and 590 pounds.

Twenty-one wildcat wells were drilled in 1938, of which four produced. Two were in Bingham Township and one in Sharon Township, Potter County, and one was in Brookfield Township, Tioga County. At the close of the year nine wildcat wells were drilling.

Digitized by Google

No test wells were completed to the Medina sandstone in 1938, but one was drilling to that horizon in Mercer County.

Four wells were drilled with rotary equipment to depths of 6,454 to 8,482 feet. The Lower Devonian formations have proved highly resistant to rotary bits.

Oriskany-sand production from Potter and Tioga Counties totaled about 25 billion cubic feet in 1938, a drop of 50 percent from 1937. This steep decline was caused by rapid depletion of reserves and failure to develop important new fields early in the year.

Production of gas from the shallow fields increased in 1938, partly offsetting the shrinkage in output from the deeper sands.

*South Dakota.*—E. P. Rothrock, State geologist, reports that no important change has taken place in the gas situation in South Dakota during 1938. The volume of production at Pierre and Fort Pierre declined slightly. Production for the year was about 9 million cubic feet. An attempt was made to have gas lines extended to cities in the James Valley as far as Aberdeen, but as yet no action has been taken.

*Texas.*—Data published by the Texas Railroad Commission indicate that natural-gas production in Texas reached a total of about 1,100 billion cubic feet in 1938, an increase of 11 percent over 1937. This figure includes about 45 billion cubic feet used for repressuring and recycling, 50.5 billion extraction loss at gasoline plants, and 137 billion blown to the air—increases over 1937 of 97, 6, and 50 percent, respectively. About 867.5 billion cubic feet of gas were used for other purposes in 1938 and 832.3 billion in 1937. Demand for gas in carbon-black manufacture declined 3 percent in 1938, pipe lines took 2 percent more, and reported use for plant fuel and lease operation increased 30 percent over 1937.

The rapid growth of repressuring and recycling is due largely to improved production methods in the high-pressure distillate fields. Inquiry into the behavior of the lighter hydrocarbons under varying conditions has revealed the great losses in recovery that may result from failure to maintain pressures above critical points in some types of reservoirs. The growing use of pressure-maintenance equipment should conserve large quantities of gas and increase yields of the liquid fractions.

The large increase in waste of residue gas in 1938 over 1937 is due chiefly to oil-production activity in flush areas where high gas-oil ratios are common. The volume blown to the air in the Panhandle was curtailed in the latter months of 1937 to an average of about 25 million cubic feet per day but averaged about 40 percent more in the last quarter of 1938. The greatest losses occurred in the South Texas district in connection with oil production. Gas reported as blown to the air amounted to about 6 million cubic feet per day early in 1937 in this area and to more than 140 million per day during the latter half of 1938. Losses in the Gulf Coast fields in 1938 were about double those of 1937. West Texas gas waste has averaged slightly less than 100 million cubic feet per day for the past 2 years. These data cover residue gas only. The volume of direct waste from producing leases is unknown. The situation has improved to the extent that more gasoline-extraction equipment is used in flush-oil fields to recover a part of the fuel value of the gas before blowing it to the atmosphere.

Digitized by Google

Completion of 341 gas wells was reported in Texas in 1938 compared with 425 in 1937. The Panhandle and Southwest Texas districts were the most active with 105 new wells each. North Central Texas and the Gulf Coast districts, with 43 and 36 new gas wells, respectively, were next in activity, followed by the East Central Texas with 25, West Texas with 16, East Texas border with 10, and East Texas with 1.

Two new gas areas were opened in the Panhandle—one in Gray County by the Fowler No. 1, which produced 25 million cubic feet of gas from the granite wash at 2,500 feet, and one in Sherman County by the Davis No. 1, which produced 30 million cubic feet from the same formation at 2,705 to 2,800 feet. In the Southwest Texas district the following distillate discoveries were reported: M. Valdez No. 1 at Banderia, Jim Wells County, 6,419 feet deep; Rooke No. 2 at La Rosa, Refugio County, which produced through perforations at 5,395 to 5,400 feet; and the American Rio Grande No. 1 at Weslaco, which produced from the Frio-Vicksburg sand at 8,634 to 8,642 feet, and the Lynn No. 1 at McAllen, which produced from 5,970 to 5,994 feet, both in Hidalgo County. Gas or distillate discoveries were reported in 10 other counties of the district.

In the West Texas district Tunstill No. 1 in Reeves County was completed in October 1938 with an initial capacity of 2.5 million cubic feet of gas from 3,274 to 3,310 feet. An 8-million cubic-foot well, Voth No. 1, was completed in July in Cooke County, North Central Texas district, from the Ellenburger limestone at 1,802 feet. A discovery in the Strawn formation, the Johnson No. 1, was completed in Eastland County, West Central Texas district, with an initial capacity of 2 million cubic feet per day from 1,482 to 1,488 feet.

Gas proration regulations were applied to Rodessa, also to the "sweet" and "sour" gas areas of the Panhandle field early in 1938. The proration law was attacked and upheld by a three-judge district court.

*Utah.*—Gas production in Utah jumped about 89 percent in 1938 over 1937 owing to increased withdrawals from the Clay Basin field, according to a report by H. J. Duncan, supervisor, Geological Survey, United States Department of the Interior. Clay Basin production, which is piped to Salt Lake City, was 3,709 million cubic feet in 1938 and 1,936 million cubic feet in 1937. The increased volume replaced part of the gas that heretofore had been produced into the same pipeline system from the Baxter Basin and Hiawatha fields, in Wyoming and Colorado, respectively. Production from the Ashley Valley field declined about 10 percent in 1938 to 44 million cubic feet; the entire output was used for domestic purposes in the vicinity.

The only gas well drilled in Utah in 1938 extended the productive limits of the Clay Basin field of Daggett County about 1 mile eastward. It was completed for 16 million cubic feet of initial capacity from the Dakota sand at 6,036 feet with a rock pressure of 2,100 pounds. There are now five gas wells in the Dakota and one in the Frontier on the Clay Basin structure.

Forty-two miles of a 52.7-mile 18-inch loop line were completed from Bigelow Hills, Wyo., to Coalville, Utah, partly paralleling the present line from Green River, Wyo., to Salt Lake City.

Very little gas was wasted or used in the field.

Digitized by Google

*Washington.*—Completion of four small gas wells in the Shallow field, 8 miles north of Bellingham, Whatcom County, marked the only gas development in Washington in 1938, according to information supplied by S. L. Glover, assistant supervisor of geology, Washington Department of Conservation. Depths of the wells ranged from 560 to 1,785 feet. The gas occurs in the Chuckanut formation with salt water, which requires the use of a separator at each well. Capacity of individual wells is only a few thousand cubic feet per day, but further development, it is hoped, will produce gas in commercially profitable amounts. The present production is distributed locally for domestic use.

Production from the Rattlesnake Hills field, Benton County, declined about 15 percent in 1938 to 121 million cubic feet valued at $75,488. Of the total, 8 million cubic feet were used in field operations and 111 million were sold to consumers in seven towns in the Yakima Valley.

Some prospecting for oil and gas was reported in 11 scattered counties.

The manufacture of dry ice from carbon dioxide near Klickitat, Klickitat County, continued to increase as in recent years, the 1938 production being 1,644,000 pounds valued at $50,740, from 13 million cubic feet of gas. All the natural springs have been abandoned in favor of shallow drilled wells which afford better control of production and larger volumes. One well recently completed at a depth of 70 feet produces enough gas for 3,600 pounds of dry ice per day.

*West Virginia.*—Drilling and pipe-line construction were considerably less in 1938 than the high level of 1937, as reported by David B. Reger, consulting geologist, Morgantown, W. Va., and R. C. Tucker, assistant State geologist. Gas-well completions totaled 504, a decline of 26 percent, but the number of successful wells in the Oriskany sand increased to 120 from 100 in 1937.

That interest in development work in West Virginia was maintained in 1938 is indicated by permits to abandon, which declined from 641 in 1937 to 570 in 1938; permits to drill, which increased from 1,034 to 1,085; and permits to deepen, which increased from 71 to 131. It is estimated that gas production in West Virginia was about 150 billion cubic feet, or approximately that of 1937.

Exploitation of the Oriskany sand continued vigorously in 1938. Important extensions were made to known producing fields, but little success attended efforts to discover new areas. In Kanawha County 120 Oriskany-sand completions were reported, of which 116 were gas wells with total open-flow capacity of 1,040 million cubic feet per day. The proved area of the three recognized pools in the county was increased to approximately 63,000 acres. The largest pool in the Elk and Poca districts, Kanawha County, was extended in 1938 into the Ripley and Washington districts of Jackson County by drilling of three gas wells in the latter districts. A wildcat well in Ravenswood district, Jackson County, gaged 337,000 cubic feet from the Oriskany with 1,600 pounds rock pressure, but completion was delayed because of lost tools. Failures in the Oriskany were drilled in the Teays Valley district, Putnam County; in the Tucker district, Wirt County; and in the Steel and Lubeck districts, Wood County. The Lubeck well showed gas in the Oriskany. Three dry wells in the Oriskany sand were drilled in Boone County, two in Jackson County, and one in Clay County.

Digitized by Google

Eight wildcat rigs were active at the close of the year in six counties.

The leading counties in gas development and the number of successful gas wells in each were: Boone 15, Braxton 10, Cabell 49, Calhoun 28, Doddridge 10, Gilmer 65, Kanawha 129, Lincoln 18, Ritchie 37, Wayne 20, and Wetzel 30. Wells completed in other sands than the Oriskany totaled 384, more than three times the number of Oriskany wells, but their initial capacity was less than a fifth that of the Oriskany wells.

A new area was opened in Barbour County by completion of a small Benson sand well north of Volga. A Clay County wildcat southeast of Villa Nova produced 510,000 cubic feet from the Webster Springs sand (upper Mississippian) at a depth of 1,708 to 1,758 feet. This sand has not heretofore been known as productive. In Wetzel County a 10-million cubic-foot well was completed in the Gordon sand north of Newdale in an area where gas has come chiefly from the shallower Maxton sand.

Considerable gas from new operations is now being moved to favorably situated old wells in Harrison, Lewis, and Taylor Counties for underground storage. A large quantity of Oriskany gas has been piped to central Ohio for storage in old Clinton-sand wells.

The price of gas in the field apparently continued the decline that has proceeded without interruption since 1931. The available supply greatly exceeds the immediate demands of present markets.

*Wyoming.*—Gross production of gas in Wyoming in 1938, including estimates of unmetered gas and that used for recycling and repressuring, was more than 38 billion cubic feet, about the same as in 1937, according to a report by H. J. Duncan, supervisor, Geological Survey, Casper, Wyo. Of the total, 1.4 percent was lost or wasted in field operations and 2.1 percent was lost in testing or controlling new wells at Beaver Creek, Big Piney, Dry Piney, and Muskrat.

Production of casinghead gas in the Salt Creek field was 10,010 million cubic feet in 1938, of which 6,833 million were returned to the reservoir after extraction of its gasoline content, leaving a net withdrawal from the field of 3,177 million cubic feet. Natural-gasoline production was about 26 million gallons, with an indicated extraction loss or shrinkage of 671 million cubic feet. Of the residue gas utilized above ground, 1,744 million cubic feet were consumed in field operations, 680 million used to generate electric power, and 81 million lost in distribution.

Gas production declined moderately in nearly all fields. Notable exceptions were Big Medicine Bow and Muskrat, whose output more than doubled. Withdrawals from Little Buffalo Basin and Little and Big Polecat were slightly larger. The largest producing fields and their 1938 production in millions of cubic feet were as follows: Big Sand Draw 4,174, Lance Creek 3,620, South Baxter Basin 3,460, Big Medicine Bow 3,206, Muskrat 2,210, North Baxter Basin 1,960, Elk Basin 1,614, and Little Buffalo Basin 1,523.

Fourteen gas wells were completed in 1938 in Wyoming (12 in 1937), of which 11 with an initial production of 133 million cubic feet per day were in old fields and 3 with an initial production of 43 million cubic feet were in new fields.

At Beaver Creek, Fremont County, a *unitized structure*, a well in sec. 3, T. 33 N., R. 96 W., was completed on April 29, 1938, with 7.8 million cubic feet of capacity and a rock pressure of 3,475 pounds from

Digitized by Google

the Morrison formation at 8,230 to 8,285 feet. The situation is near a pipe line, but there is no immediate market for the gas.

A discovery well was completed on June 21, 1938, on the Oil Springs structure, Carbon County (sec. 3, T. 23 N., R. 79 W.), which produced 19.3 million cubic feet initially with a rock pressure of 1,100 pounds from the Sundance formation at 2,222 to 2,315 feet. A second well, completed in sec. 2 on December 6, had an initial open-flow capacity of 16 million cubic feet from the same horizon.

At Big Piney and Dry Piney, both in Sublette County, southwestern Wyoming, gas blow-outs that occurred during the drilling of wildcat wells indicate the possibility of gas accumulations. However, the area is sparsely populated and remote from markets. Drilling operations will continue in 1939 at both wells.

New gas reserves were discovered in the Muskrat field, Fremont County, by a well in sec. 4, T. 33 N., R. 92 W., which made 40 million cubic feet of gas from the Lakota sand at 5,306 to 5,320 feet. At Elk Basin the deepening of an old well resulted in a 73-million cubic-foot flow of gas which increased the available supply for the pipe line to Billings, Mont. Four wells drilled at Baxter Basin had a combined open-flow capacity of 15 million cubic feet per day.

The production from Lance Creek before December 16, 1937, was used mainly in a carbon-black plant, but under a unit plan effective January 1, 1938, it is now used in drilling, repressuring, and field activities. About 1 billion cubic feet of the Lance Creek output in 1938 were used in field operations, about 2.5 billion were utilized in repressuring, and 75 million cubic feet were lost or wasted. No carbon-black plants are now operating in Wyoming.

Gas wells connected to existing pipe lines are adequate for immediate needs. Increased use of natural gas may be provided through increased repressuring activities in some of the larger oil fields.

## CONSUMPTION

Less natural gas was used in 1938 by all classes of consumers except petroleum refineries and electric-power plants. The decline in miscellaneous industrial consumption was sharpest, about 15 percent, and was particularly marked in the manufacturing sections of East-Central United States. Domestic consumers used 16 percent of the gas in 1938 and 15 percent in 1937. Industrial consumption took 79 and 80 percent of the total, respectively.

[1] Includes natural gas piped from Canada.

In 1937 increased consumption of natural gas was general in all parts of the country. The sharpest gains over 1936 were in Arizona, Arkansas, Michigan, New Mexico, and Texas.

Domestic consumers of natural gas numbered 8,348,000 and commercial consumers 680,000 at the end of 1937. These totals were

Digitized by Google

4.1 and 3.5 percent larger than at the end of 1936. Further growth doubtless took place in 1938.

*Treated for natural gasoline.*—The volume of natural gas processed at natural-gasoline plants in 1938 was about 2,115 billion cubic feet, estimated on the basis of an average recovery of 1 gallon per thousand cubic feet. In 1937, 2,108.8 billion cubic feet were processed, equal to 88 percent of total consumption. The volume processed in 1938 was 94 percent of the consumption. The gain in percentage reflected the efforts of natural-gasoline manufacturers to increase their supplies.

Pronounced increases in volume handled in 1937 over 1936 in California, New Mexico, and Texas continued through 1938. In Oklahoma and Louisiana, however, the volume was considerably less in 1938 than in 1937.

*Natural gas treated at natural-gasoline plants in the United States, 1933–37, by States*

[1] Exceeds 100 percent, as part of the natural gas treated for natural gasoline is blown to the air and not included in total consumption.

*Domestic and commercial.*—Domestic use of natural gas fell about 3 percent in 1938. Demand is estimated at 362 billion cubic feet compared with 372 billion in 1937. As the number of domestic meters in use was greater in 1938 than in 1937, the average consumption per meter declined more abruptly than did the total consumption. In a few States, notably California, Michigan, and Indiana, volume of domestic sales increased. The estimated average value of gas purchased by domestic consumers in 1938 was 74.0 cents per thousand cubic feet, slightly above the comparable figure for 1937 of 73.6 cents. The total value of domestic sales was about $267,880,000 in 1938 compared with $273,577,000 in 1937.

Commercial consumption declined about 3 percent in 1938 to 114 billion cubic feet. The average value at points of consumption is estimated to have advanced to 49.0 cents per thousand cubic feet from the 1937 average of 48.7 cents, indicating a total value in 1938 of $55,860,000.

The weather in the United States in 1938 was unseasonably warm during the months of heavy gas consumption. This factor undoubtedly reduced somewhat the demand from domestic and commercial customers.

*Field.*—Field operations are estimated to have consumed 620 billion cubic feet of natural gas in 1938, 5 percent less than the 1937 total of 651 billion. Field use decreased in most States, but the most pronounced drop probably was in Oklahoma and Kansas. Active oil development in Illinois and Arkansas doubtless caused marked increases in field consumption in those States. In 1937 the three most important oil-producing States, Texas, California, and Oklahoma, with 76 percent of the United States output, used 541 billion cubic feet of gas for field purposes.

*Carbon black.*—The volume of natural gas burned in carbon-black manufacture in 1938 was 325 billion cubic feet, almost 5 percent less than in the record year 1937. Consumption in Texas declined only 0.5 percent and that in Louisiana 39 percent. The use of gas in carbon-black plants in the Monroe field of Louisiana has been decreasing for several years. The gas used in Oklahoma, Kansas, and Wyoming, the only other States producing carbon black, totaled slightly more in 1938 than in 1937 but represented only 3 percent of the national total.

*Petroleum refineries.*—The volume of natural gas consumed at petroleum refineries in 1938 is estimated to have increased about 8 percent over 1937 to 122 billion cubic feet. Although crude runs to stills at refineries in the United States as a whole were slightly less in 1938 than in 1937, they increased considerably in some of the districts where natural gas is used most widely as a refinery fuel. The refineries of Texas and California are by far the most important users of natural gas for this purpose. The use of natural gas at refineries has grown rapidly since 1933 when only 66 billion cubic feet were consumed.

*Electric public-utility power plants.*—A total of about 171 billion cubic feet of natural gas was used in 1938 to generate electric power at public-utility power plants, about the same quantity as in 1937. Therefore, the relative importance of natural gas as a source of energy in electric-power production increased somewhat in 1938, as the total consumption of all fuels was 9 percent less than in 1937. On the basis of the B. t. u. content of fuels consumed, natural gas supplied 13.8 percent of the total heat energy utilized in 1938 and 12.6 percent in 1937. Factors used in calculating the B. t. u. values of fuels were 26 million B. t. u. per short ton of coal, 6 million B. t. u. per barrel of fuel oil, and 1,050 B. t. u. per cubic foot of natural gas.

*Portland-cement plants.*—Natural gas consumed at portland-cement plants in 1938 totaled about 37 billion cubic feet, a decline of 8 percent from 1937. The reduction in demand was due to curtailment of cement production, which fell about 10 percent in 1938 in common with most industrial activities. Cement plants in the Mid-Continent area and Texas are the principal users of natural gas, probably owing to the low price for industrial gas in those sections.

*Other industrial.*—Depressed business conditions, which were felt particularly during the first three quarters of 1938, reduced substantially the demand for natural gas for miscellaneous industrial uses. It is estimated that "other industrial" demand in 1938 declined about 15 percent from 1937 to 510 billion cubic feet. Curtailment was particularly severe in Ohio, Pennsylvania, and West Virginia, where the steel and ceramic industries are large consumers.

Improved equipment and technique in utilization of natural gas in industry have brought about greater efficiency in the transfer of heat. A "hot tube" type of combustion apparatus has been developed which eliminates contact between the flue gases and the material being heated. A new industrial outlet for gas may develop from the invention of a new fabric similar to silk and said to be superior in some respects. Natural gas is a principal ingredient.

*Mixed gas.*—The volume of natural gas sold to consumers in 1937 for blending with manufactured gas declined 12 percent to 56 billion cubic feet from a 1936 total of 64 billion. The principal cause of the drop was a change in the Detroit area from the use of mixed to natural gas, which resulted in the transfer of about 400,000 meters to the straight natural-gas classification. The number of consumers in Iowa and Ohio also was reduced slightly in 1937.

Illinois consumes almost 40 percent of the natural gas sold with manufactured gas, as the Chicago metropolitan area is served with mixed gas. New York State is the second largest consumer of mixed gas, which is sold extensively in Buffalo and vicinity.

*Consumption of natural gas used with manufactured gas in the United States in 1937, by States*

## INTERSTATE SHIPMENTS

Interstate pipe lines carried 687 billion cubic feet of gas across State lines in 1937, an increase of approximately 20 percent over 1936. The volume of the interstate movement equaled 29 percent of total marketed production in 1937, 26 percent in 1936, and 24 percent in 1935.

Texas, Louisiana, and West Virginia, furnished 67 percent of all interstate shipments in 1937 and 69 percent in 1936. Several States of secondary importance as producers of gas increased their share of the total market. Among these, Kentucky and Pennsylvania each transported about 35 percent more gas to other States in 1937 than in 1936, Oklahoma 31 percent, New Mexico 29 percent, and New York 247 percent. Shipments to other States increased in all States except

Digitized by Google

those from Colorado, Illinois, Indiana, and Ohio. The movement of a small amount of gas from Utah to Wyoming began in 1937. Substantial increases were reported in transportation of gas from New Mexico to Arizona, New York to Pennsylvania, and Pennsylvania to West Virginia.

Receipts of gas from other States gained moderately in Ohio and Illinois, the most important consumers. Ohio absorbed 82.7 billion cubic feet, of which 73.4 billion came from West Virginia and 8.7 billion from Kentucky. Illinois absorbed 77.6 billion, of which 57 billion came from Texas, 17.4 billion from Louisiana, and 3 billion from Kansas. Shipments into Michigan, which originated chiefly in Texas and Kansas, grew spectacularly from 4 billion in 1936 to 15 billion cubic feet in 1937 owing to the opening of the Detroit market to natural gas late in 1936.

Most Texas gas exports are from the Panhandle area. It will be noted from the following table that large volumes of gas are piped from Louisiana into Texas to serve markets in the eastern part of the State. The position of Kansas is unique among States whose developed gas reserves greatly exceed current needs. Gas piped into Kansas from Texas and Oklahoma has been substantially larger than outgoing volume in every recent year. In 1937 such imports were 56.3 billion cubic feet and exports 43.3 billion.

## PIPE-LINE DEVELOPMENTS

Total mileage of natural-gas pipe lines built in 1938 was only about one-third of that in 1937. No major lines were constructed. Most new lines were laid to connect developed gas reserves to existing transportation systems. A few minor extensions were made to serve new markets.

The largest project reported comprised 53 miles of 18-inch pipe running from Bigelow Hills, Wyo., to Coalville, Utah. It serves principally as an added loop to the main line which supplies the Salt Lake City (Utah) market. Seven short lines were built in Texas, which ranged in length from 11 to 48 miles and most of which provided new outlets for gas fields.

A 14-mile 8-inch line was laid from Merced to Livingston, Calif., and 10 miles of 10-inch pipe were laid in the Montebello oil field. In Oklahoma, 14 miles of 10- and 12-inch line were installed between Cement and Chickasha. The Schuler oil field in Arkansas supplied gas to a 6-inch line to Eldorado, a distance of 18 miles. An extension of 39 miles of 16-inch pipe was made to a major pipe-line system from Ventura, Iowa, to Albert Lea, Minn.

In Pennsylvania 27 miles of 8-inch pipe were installed from the new Summit Hotel gas field to Waynesburg. Twenty-four miles of 16-inch line were laid from Howard to Perrysville, Ohio.

At least 60 percent of the gas lines of 6-inch and larger sizes that were built in 1938 were coupled by means of electric welds. A new technique for making pipe bends in the field attained rather wide favor in 1938. It is called wrinkle bending and involves heating strips of the pipe wall at right angles to the axis of the pipe to facilitate bending. It effects economies over older methods, as less equipment and smaller crews are required and somewhat less time is consumed per bend. A procedure has been developed for relieving the stresses that are normally produced in arc welds because of rapid temperature changes over a wide range. Stronger, more uniform welds result.

It has been found advantageous under certain conditions to build bridges to carry pipe lines across rivers rather than to embed the line below the river. This practice has become particularly important in parts of the Southwest where river channels are variable owing to shifting sands and where the river waters corrode steel pipe.

## NATURAL GASOLINE

In 1938 the natural-gasoline industry, like most branches of the oil-and-gas industry, experienced a satisfactory year from the standpoint of production, stocks, and distribution, but profits were generally disappointing. This was largely because the low prices carried over from 1937 failed to rally until late in the year.

*Salient statistics of the natural-gasoline industry in the United States, 1934–38, in thousands of gallons*

[3] Production plus or minus changes in stocks.
[4] Including amounts run through crude-oil pipe lines east of California.

[1] Data for 1938 are preliminary; detailed statistics with final revisions will be released later.

Digitized by Google

Production in 1938 was probably about 2,125,000,000 gallons (the preliminary total was 2,113,314,000 gallons), or about 60 million gallons above the final figure for 1937. However, the 1938 production was about 5 percent short of the record totals of 1929 and 1930. Texas failed to displace California as the leading producing State in 1938, as had been predicted, but as the gap between their outputs was closed in the middle of the year it is probable that Texas will be the leader in 1939.

The natural-gasoline industry maintained its position as a source of volatility in refinery gasoline, but at the expense of further reduction of the average vapor pressure and at generally lower prices. Exports of natural gasoline rose in spectacular fashion during 1938, but "direct" sales were lower than in 1937.

The average yield of natural gasoline declined slightly in 1937 but is believed to have increased in 1938 to about 1 gallon per thousand cubic feet of gas treated. The outstanding technical development of the year probably was the construction of a number of recycle plants—

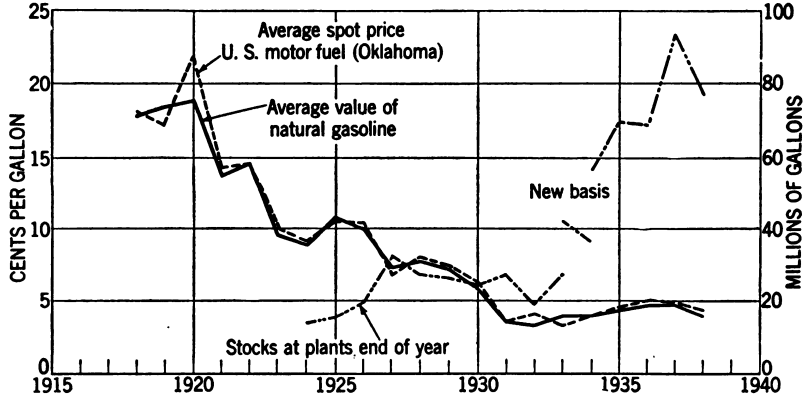

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–38.

installations that recover gasoline from so-called distillate wells and return the residue gas to the producing formations. Adjunctive to this development were improvements in the absorption process involving higher pressures and advanced refrigeration.

## PRICES AND MARKET CONDITIONS

The price levels for natural gasoline were generally disappointing in 1938, although the fact that closing quotations on December 31 were higher than those at the first of the year was encouraging. The opening price of a representative grade of natural gasoline (26–70 in Oklahoma) was 3.00 cents per gallon on January 1, reached the year's low of 2.00 cents in February, and started a definite recovery in July which was maintained for the remainder of the year.

As shown in figure 1, the average value of natural gasoline has been below that of the cheapest grade of U. S. Motor gasoline in Oklahoma since about 1934. In 1938 the price differential widened to about 0.5 cent per gallon from about 0.2 cent in 1937, indicating a set-back for natural gasoline in competition with certain light refinery products.

## EMPLOYMENT AND PRODUCTIVITY

The number of natural-gasoline plants has declined in recent years, but up to January 1, 1938, the capacity and number of workers employed increased steadily. This capacity (measured biennially) gained about 15 percent in the 2-year period, 1936–37. The average number of workers rose from 9,198 in 1936 to 9,429 in 1937, a gain of 3 percent. A loss of 5 percent or more in employment in 1938 is anticipated.

Part-time employment at natural-gasoline plants is relatively unimportant; in fact, many companies apparently never have part-time workers. The total number of part-time workers declined from 1,008 in 1936 to 734 in 1937, probably owing to a reduction in men engaged in new construction and replacement.

The hours per week of full-time workers at natural-gasoline plants are virtually the same as those of oil-field workers. In 1936 the average was 40.1 hours per week and in 1937, 41.3. The part-time employees worked about half the time—that is, nearly 1,000 hours a year. The production of natural gasoline increased more rapidly in 1937 than the number of man-hours of work, hence average productivity increased. The average productivity per man-hour in 1937 was 106.6 gallons compared with 99.6 gallons in 1936.

## PRODUCTION

*Trends in total output.*—Except in 1933, when the East Texas field upset a number of precedents, the trend of natural-gasoline production over the last decade has conformed closely to that of crude-oil production. (See fig. 2.) In 1938, however, the output of crude oil declined 5 percent, whereas that of natural gasoline gained 2 percent. Increased yields in 1938 were no doubt responsible for this anomaly, although curtailment in crude-oil production is not followed generally by as large a decline in the output of casinghead gas.

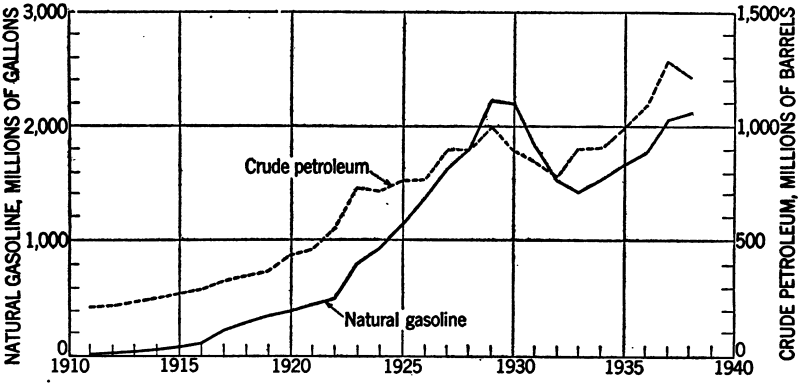

FIGURE 2.—Annual production of natural gasoline and crude petroleum, 1911–38.

The trend in daily average output of natural gasoline in 1938 was generally downward until August and September, after which an upward swing brought the average at the end of the year to just about what it was on January 1.

*California.*—Production in California continued the annual increase begun in 1934, the output in 1938 being 664,000,000 gallons (6 percent above 1937). The actual increase may have been as high as 8 percent, because the 1938 figures are subject to material revision.

The chief factor affecting natural-gasoline production in California in 1938 was the degree of curtailment in crude-oil production. Strenuous efforts of the proration committees were rewarded with some decreases in crude-oil production in the middle and last quarter of the year, after which natural-gasoline production declined accordingly. The older fields of California just about held their own in production in 1938, Long Beach being a notable exception.

*Louisiana.*—Owing to the decline in output of the Rodessa oil field natural-gasoline production in Louisiana fell to 86,700,000 gallons in 1938 from 106,400,000 gallons in 1937. The crude-oil output of the State increased, but the gain was in the coastal fields where there are few natural-gasoline plants and where most of the gas is wasted.

*Oklahoma.*—Production decreased 5 percent in 1938, or from 492,300,000 gallons in 1937 to 468,500,000 in 1938. The "Rest of State", composed of many small fields outside the three major areas, increased its output but not enough to offset the material loss at Oklahoma City.

*Texas.*—Production in Texas continued to increase, the total of 655,800,000 gallons in 1938 being 7 percent above the previous peak in 1937. Although the Texas total for 1938 was slightly below that of California, indications are that Texas already has become the leading producing State, as it surpassed California in monthly output the middle of the year.

In 1938 production in the Panhandle and East Texas, the two leading districts, was virtually the same as in 1937. The output increased in "Rest of State" and in the Gulf Coast district, where considerable natural gasoline is produced incident to recycling operations.

*Other States.*—Production in most of the other producing States decreased in 1938, Arkansas and New Mexico being the chief exceptions. In Arkansas the discovery of deep oil production has greatly increased the available supply of casinghead gas, and the output in 1938 was more than double that in 1937. Michigan increased production in 1938, but Illinois proved an exception to the general rule that natural-gasoline output follows the general trend of crude-oil yield. The output of crude oil in Illinois in 1938 was more than 200 percent higher than in 1937, yet the production of natural gasoline declined, because the gas-oil ratios of the new fields are relatively low; furthermore, most of the production is so scattered that the companies burn it in flares rather than go to the expense of piping it.

*Natural gasoline produced and natural gas treated in the United States in 1937, by States* [1]

| State | Number of operators [2] | Number of plants operating | Natural gasoline produced | | | Natural gas treated | |

[1] Complete figures for 1938 not yet available.
[2] A producer operating in more than 1 State is counted only once.

## CONSUMPTION AND MOVEMENTS

The indicated demand or distribution of natural gasoline in 1938 was about 2,110,000,000 gallons—4 percent higher than in 1937. The demand in 1938 was divided as follows: Utilized at refineries, 80 percent; exports, 10 percent; direct shipments to jobbers and retailers, 6 percent; and losses, 4 percent. Compared with similar data for 1937 these ratios indicate chiefly an increase in the importance of exports at the expense of refinery consumption.

*Refinery utilization.*—The proportion of natural gasoline in refinery gasoline continued to increase, rising to 7.2 percent in 1938 from 7.0 percent in 1937. This does not necessarily mean that the product was more indispensable in refinery operations but simply that the output of producers without refining facilities was absorbed at lower prices.

The two Gulf Coast districts, in which blending increased materially in 1937, used considerably less natural gasoline in 1938. On the other hand, California and Texas Inland, the two districts with the highest blending ratios, used even more natural gasoline in blending in 1938.

*"Direct" sales.*—Although it might seem that the low refinery prices would have spurred producers to market low-vapor-pressure material direct to consumers, the quantity sold to jobbers and retailers declined from 143,640,000 gallons in 1937 to 137,970,000 in 1938. On the other hand, shipments to refinery-owned bulk plants increased from 27,869,000 gallons in 1937 to 39,270,000 in 1938.

The largest single interstate movement of natural gasoline to consumers other than refiners continued to be that from Oklahoma to Illinois; and the largest intrastate movement, that within Texas. Both movements increased in 1938 over 1937. "Direct" sales in Arkansas increased materially in 1938, whereas those in Kansas showed a severe decline.

*Shipments of natural gasoline to jobbers, retailers, and refinery-owned bulk plants in the United States in 1938, by States, in thousands of gallons* [1]

*Water-borne shipments.*—Data reported to the Bureau of Mines by manufacturers indicate total exports of 202,230,000 gallons (4,815,000 barrels) in 1938 compared with 148,428,000 gallons in 1937. The figures of the Bureau of Foreign and Domestic Commerce for exports are 3,738,000 barrels for 1937 and 6,114,000 for 1938. The sizable difference in the respective totals for 1938 probably represents natural gasoline mixed with crude oil for export, a practice that is reported to have grown rapidly in 1938. Exports of natural gasoline from California in 1938 remained about the same as in 1937, hence the large gain was recorded in exports from the Gulf. Shipments for blending at refineries in Netherland West Indies comprised the largest single item in 1938, with exports to United Kingdom, France, and Canada following in that order. Japan took 384,000 barrels in 1938 but Germany and Italy together only 64,000 barrels. About 70 percent of the total exports of natural gasoline in 1938 passed through the Galveston (including Houston) customs district.

## STOCKS

Substantial withdrawals in the last 3 months of 1938 eased the stock situation, as the total rose only about 3,000,000 gallons—from 199,836,000 gallons on January 1 to 202,860,000 gallons on December 31. The gain was in refinery stocks, as stocks at plants and terminals declined about 16,000,000 gallons. More specifically, the responsibility for the increase rests with refinery stocks in California, which

Digitized by Google

rose from about 82,000,000 gallons on January 1 to about 109,000,000 on December 31. Stocks at other points apparently reached unprecedented low levels, at least in terms of days' supply, which should be a helpful factor throughout 1939.

## TECHNICAL DEVELOPMENTS

*Yields.*—The upward trend in yields was arrested in 1937 when the national average was 0.98 gallon per thousand cubic feet compared with 0.99 gallon in 1936. However, indications are that the average yield will increase to at least 1.00 gallon in 1938, despite a decrease in average vapor pressure. The average yield in California and Texas, the two leading producers, gained in 1937 but not enough to overcome losses in Oklahoma and New Mexico.

*Production by processes.*—The number of straight compression plants continued to decline, but the production by this process (including vapor rectification) continued to rise. Production by the absorption (and combination) methods increased materially in 1937, and the process gave no evidence of decreasing in popularity. The number of charcoal plants was one less (10 to 9), and the total production by this method decreased after an unexpected gain in 1936.

[3] Drip gasoline.

*Trends in vapor pressures.*—The weighted average vapor pressure of all shipments of natural gasoline continued to decline, falling to 19.6 pounds in 1938 from 20.0 pounds in 1937. The decrease was chiefly in refinery shipments, as the average vapor pressure of exports rose 0.1 pound (17.1 to 17.2 pounds) while that of "direct" shipments fell only 0.1 pound (15.7 to 15.6 pounds). The downward trend in vapor pressures reflects the constant effort required to keep natural gasoline a primary source of volatility at refineries. Unfortunately, reducing the butane content to make a more stable product generally lowers the octane rating, hence the interest of the industry in such matters as compression ratios, volatility specifications, and carburetor design.

*Technical improvements.*—No figures on polymerization were collected in 1938, but it is safe to say that application of the process expanded materially. However, most of the expansion was at refineries, that at natural-gasoline plants remaining the exception. The desire to maintain the position of natural gasoline in the octane race was the prime motive in experiments by which isopentane, a high-octane product, was made from natural gasoline by polymerization. The idea apparently has possibilities, but its application is still in the experimental stage.

Probably the most important improvements in established methods were those permitting the use of much higher pressures in the absorbers. This development was of particular significance where the gas was returned to the sand. Higher yields at absorption plants are being obtained by advanced refrigeration, through which the lean oil is cooled by the expansion of butane-propane mixtures.

## LIQUEFIED PETROLEUM GASES [2]

Despite uncertain economic conditions during 1938, sales of liquefied petroleum gases continued to gain although at a lower rate than in recent years. Domestic deliveries in 1938 were 165,201,000 gallons compared with 141,400,000 gallons (revised) in 1937.

*Sales of liquefied petroleum gases, 1933–38, in thousands of gallons*

| Year | Propane | Butane | Propane-butane mixtures | Pentane | Total |
|---|---|---|---|---|---|
| 1933 | 15,835 | 19,056 | 3,226 | 814 | 38,931 |
| 1934 | 18,681 | 25,553 | 10,271 | 1,922 | 56,427 |
| 1935 | 26,814 | 34,084 | 13,493 | 2,464 | 76,855 |
| 1936 | 36,502 | 40,200 | 27,375 | 2,575 | 106,652 |
| 1937 | 46,474 | [1] 45,399 | 46,694 | 2,833 | [1] 141,400 |
| 1938 [2] | 54,130 | 52,768 | 56,050 | 2,253 | 165,201 |

[1] Revised figures. [2] Subject to revision.

All principal uses for liquefied petroleum gases were greater in 1938 than in 1937 except deliveries for industrial fuel, which declined in 1938 owing to generally curtailed manufacturing operations. Sales of liquefied petroleum gases for domestic consumption expanded noticeably in 1938, increasing 42 percent as the advantages of this type of fuel for cooking, heating, air conditioning, refrigeration, power, and lighting for the home, the farm, the camp, and the small establishment became known more widely. Requirements for chemical manufacturing and internal-combustion-engine fuel mounted more than 20 percent in 1938 compared with 1937, while sales of liquefied petroleum gases to gas-manufacturing companies in 1938 were 11 percent above the 1937 total. Exports of liquefied petroleum gases continued the decline of recent years and were reported as 825,000 gallons in 1938 compared with 1,984,000 gallons in 1937 and 5,125,000 gallons in 1936. The marketed production of liquefied petroleum gases, including both domestic and export deliveries, totaled 166,026,000 gallons in 1938, or 16 percent over the 1937 requirements of 143,384,000 gallons.

In 1938, as in 1937, total deliveries of liquefied petroleum gases were divided about equally among propane, butane, and propane-butane mixtures, while pentane sales remained relatively unimportant. Propane sales of 54,130,000 gallons in 1938 were 16 percent above the 1937 total of 46,474,000 gallons, while butane deliveries of 52,768,000 gallons in 1938 likewise were 16 percent more than in 1937. The market for propane-butane mixtures increased from 46,694,000 gallons in 1937 to 56,050,000 in 1938, or 20 percent. Sales of pentane, which declined for the first year since 1933, were reported as 2,253,000 gallons in 1938 compared with 2,833,000 in 1937.

A review of 1938 sales of liquefied petroleum gases reveals that the domestic or "bottled-gas" demand took the lead over industrial-fuel requirements. Domestic sales of 57,832,000 gallons in 1938 represent 35 percent of total deliveries compared to 29 percent in 1937. It should be noted, however, that this reversal in the market demand probably is temporary, as 1938 was a year of retarded ac-

[2] By A. T. Coumbe, Petroleum Economics Division, Bureau of Mines.

Digitized by Google

tivity in manufacturing. Consequently requirements for industrial fuel were somewhat below normal, as shown by deliveries of 38,849,000 gallons in 1938—10 percent less than the 1937 total of 43,310,000 gallons. The extent of the decline in the use of liquefied petroleum gases in 1938 for industrial fuel is illustrated further by the fact that this particular use constituted about 31 percent of the total demand in 1937 but less than 24 percent in 1938.

Sales of liquefied petroleum gases to gas-manufacturing companies for direct resale through their mains or for mixture with other gases increased 11 percent in 1938 to a total of 12,386,000 gallons. Deliveries for this use, however, declined from 7.9 percent of the marketed production in 1937 to 7.5 percent in 1938. Sales of liquefied petroleum gas credited to chemical manufacturing were 32,299,000 gallons in 1938, or 21 percent over 1937 sales of 26,792,000 gallons, but the 1938 increase was much less than that in 1937, when sales for this purpose virtually doubled the 1936 quantity (14,445,000 gallons). The steady growth in the sale of liquefied petroleum gases for use as fuel in internal-combustion engines continued in 1938, when 20,914,000 gallons were delivered—a gain of 23 percent over the 1937 demand of 16,987,000 gallons. Liquefied petroleum gases have proved quite satisfactory as fuel in heavy-duty automotive equipment and power engines, so further development along this line may be expected.

The market for propane increased from 46,474,000 gallons in 1937 to 54,130,000 gallons in 1938. In 1938, as in previous years, the bulk of the propane was delivered for domestic consumption, the quantity increasing from 30,436,000 gallons in 1937 to 37,556,000 in 1938. Propane sold for industrial fuel declined slightly from 14,490,000 gallons in 1937 to 14,316,000 in 1938, while that delivered for gas manufacturing increased noticeably from 1,077,000 gallons in 1937 to 1,491,000 in 1938.

Sales of butane increased 16 percent—from 45,399,000 gallons in 1937 to 52,768,000 in 1938. Butane is in greatest demand as an industrial fuel where temperature control in manufacturing processes is important; however, because of the slower industrial pace in 1938, this use declined from 28,071,000 gallons in 1937 to 23,405,000 in 1938. The domestic consumption of butane, which doubled in 1937 compared with 1936, continued the sharp upward trend in 1938, when sales increased to 13,194,000 gallons from 6,047,000 in 1937. It is also of interest that domestic use ranked second as an outlet for butane in 1938, supplanting gas manufacturing which dropped to third place. The rapid growth in the domestic demand for butane is confined largely to the South Central States, where petroleum refineries and gasoline plants furnish a ready supply. Butane predominates in deliveries of liquefied petroleum gases to gas-manufacturing companies, and 8,270,000 gallons of this gas were sold for gas manufacturing in 1938 compared with 7,325,000 gallons in 1937. Sales for this use in 1938 were exceeded only by deliveries of butane for industrial and domestic consumption. The use of butane as fuel in internal-combustion engines gained sharply in 1938, when 5,025,000 gallons were reported compared with 1,715,000 gallons in 1937. Furthermore the percentage of butane in internal-combustion-engine fuel increased from 10 percent in 1937 to 24 percent in 1938.

Digitized by Google

Propane-butane mixtures are important as solvents and raw material to chemical manufacturers who buy more than half of the marketed production. Data released now for the first time show that the demand for propane-butane mixtures for use in chemical manufacturing totaled 12,223,000 gallons in 1936 and doubled to 24,601,000 gallons in 1937. The increase was not as spectacular in 1938 owing to adverse economic conditions; however, 30,496,000 gallons of propane-butane mixtures were absorbed in the manufacture of chemicals during the year. Propane-butane mixtures make an ideal internal-combustion-engine fuel under some conditions of service and load, and developments in that direction have made rapid progress. Sales of propane-butane mixtures for motor fuel increased from 14,994,000 gallons in 1937 to 15,509,000 in 1938, the larger share of the demand in both years being reported for the Pacific Coast States. Propane-butane mixtures are relatively unimportant as a domestic fuel; however, sales for that use increased from 3,504,000 gallons in 1937 to 6,316,000 in 1938.

Pentane sales declined from 2,833,000 gallons in 1937 to 2,253,000 in 1938. The consumption of pentane by chemical plants dropped from 1,907,000 gallons in 1937 to 1,413,000 in 1938, and domestic sales fell from 836,000 gallons in 1937 to 766,000 in 1938.

The American Gas Association has cooperated in the current annual survey of the marketed production of liquefied petroleum gases by reporting the pertinent details of the distribution by gas companies as follows:

At the end of 1938, liquefied petroleum gas was being delivered through mains to consumers in 193 communities in 31 States by 80 companies supplying 38,400 customers.

Butane-air gas with heating value ranging from 520 to 900 B. t. u. per cubic foot was supplied to 140 communities in 30 States by 70 companies. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cubic foot was supplied to 13 communities in California by 5 companies. Undiluted propane gas with a heating value of 2,550 B. t. u. per cubic foot was supplied to 40 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia, and Wisconsin by 6 companies.

A gain from 21 percent in 1937 to 22.5 in 1938 in cylinder or drum shipments of liquefied petroleum gases is associated with the large increase (42 percent) in domestic sales. This is substantiated by the reported data that show cylinder shipments for domestic use of 35,424,000 gallons out of total cylinder shipments for all uses of 37,140,000 gallons in 1938 compared with cylinder shipments for domestic use of 26,097,000 gallons out of total shipments of 29,926,000 gallons in 1937. Largely because of contracted industrial requirements, bulk handling of liquefied petroleum gases in tank cars and tank trucks declined from 78.8 percent of total deliveries in 1937 to 77.5 percent in 1938.

Forty distributors of liquefied petroleum gases reported their sales to the Bureau of Mines in the 1938 survey compared with 33 in 1937. In the Pacific Coast area 11 companies responded to the request compared with 10 in 1937.

# CARBON BLACK

By G. R. Hopkins and H. Backus

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1069 | Demand | 1073 |
| Salient statistics | 1070 | Total deliveries | 1073 |
| Production | 1070 | Domestic consumption | 1073 |
| By States, districts, and months | 1070 | Exports and imports | 1074 |
| Methods and yields | 1072 | Stocks | 1076 |
| Number and capacity of plants | 1072 | Prices and values | 1076 |
| Producers | 1072 | | |

The year 1938 was not a particularly prosperous one for the carbon-black industry. Compared with 1937 domestic sales and exports dropped 20 and 9 percent, respectively. However, the most depress-

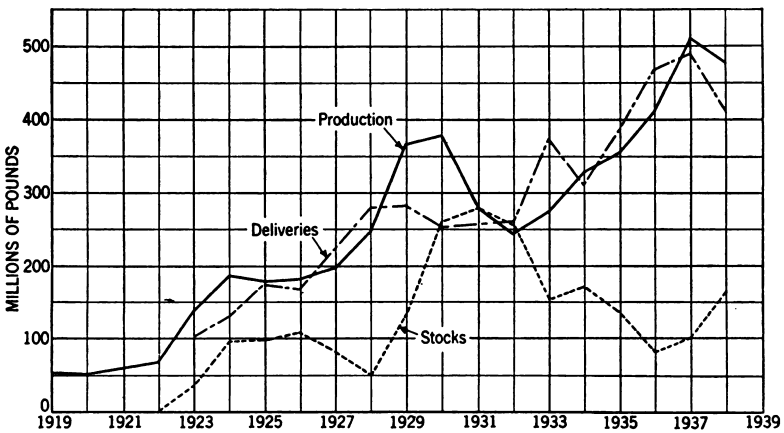

FIGURE 1.—Production, stocks, and deliveries of carbon black, 1919–38.

ing feature was the decline in price; the average f. o. b. plant value fell from 3.41 cents per pound in 1937 to 2.41 cents in 1938. The severe break in prices occurred in the last half of 1937, when rubber consumption was falling rapidly. Recovery in the rubber industry was gradual in 1938, but competitive conditions, plus sharp declines in sales for ink, paint, and miscellaneous uses prevented any substantial late-season rise in carbon-black prices. The situation was complicated further by the insistence of tank-car shippers that the quotations reflect their lower handling costs.

As shown in figure 1, production declined in 1938 for the first time since 1932. Stocks increased substantially in 1938 but at the end of the year were far below the depression peaks of 1930–32.

## PRODUCTION

*By States, districts, and months.*—The decline in output in 1938 was general throughout all producing States, Oklahoma being the chief exception. Louisiana's output showed a material decrease (40 percent) but that of Texas nearly held its own, dropping only from 421,068,000 pounds in 1937 to 417,104,000 pounds in 1938. Production in the Texas Panhandle declined in 1938 for the first time since 1932, but increased activities in West Texas raised the output in "Rest of State" from 15,821,000 pounds in 1937 to 34,735,000 pounds in 1938.

According to estimates based on monthly figures of the National Gas Products Association, the average daily output of carbon black declined until about midyear then partly recovered under the stimulus of buying at bargain prices.

Digitized by Google

*Methods and yields.*—Output by processes other than the regulation channel process dropped from 66,179,000 pounds in 1937 to 35,755,000 pounds in 1938, whereas production by the channel process decreased only from 444,427,000 to 441,284,000 pounds. Apparently the producers of high-yield retort blacks, which comprise the major part of the production of "other types," preferred to lose some of their market rather than meet all cuts in the price of channel black.

The yield of carbon black, which reached a peak of 1.50 pounds per thousand cubic feet in 1937, fell to 1.47 pounds in 1938. Doubtless this decrease was related to the material decline in production by special processes, some of which have relatively high yields.

Research on carbon black by producers and consumers was perhaps intensified in 1938. Much of the research resulted in narrowing the specifications for use of carbon black in rubber. The relative proportion of "dustless" production continued to increase rapidly; and a collateral development, shipments in bulk, grew as fast as finances would permit.

*Number and daily capacity of carbon-black plants operated in the United States, 1937–38, by counties or parishes*

| State | County or parish | Number of plants | | Total daily capacity (pounds) | |

[1] Kansas and Wyoming included with Oklahoma.
[2] 1 plant, located in both Carson and Hutchinson Counties, counted in Hutchinson County.

*Number and capacity of plants.*—The construction of new capacity for the manufacture of carbon black was at a standstill in 1938, which was natural in view of the overproduction and low prices. No new plants were built; on the other hand three were removed from the operating list as either dismantled or shut down.

The total capacity of the operating plants remained virtually constant in 1938 at about 1,736,000 pounds daily. A decline of about 7,000 pounds in capacity in Louisiana was compensated by a similar gain in Texas. The ratio of operating capacity to total plant capacity declined from 81 percent in 1937 to 75 percent in 1938.

*Producers.*—Carbon-black producers in 1938 were essentially the same as shown in Minerals Yearbook 1938 except that the Dewdrop

Digitized by Google

plant of the United Carbon Co., the Pampa plant of the Magnolia Petroleum Co., and the Pioneer plant of the Peerless Carbon Black Co. were removed from the list as either inoperative or dismantled.

## DEMAND

*Total deliveries.*—Sales of carbon black in 1938 totaled 411,442,000 pounds, 16 percent less than in 1937. Domestic sales in 1938 were 243,474,000 pounds and exports 167,968,000 pounds, indicating a

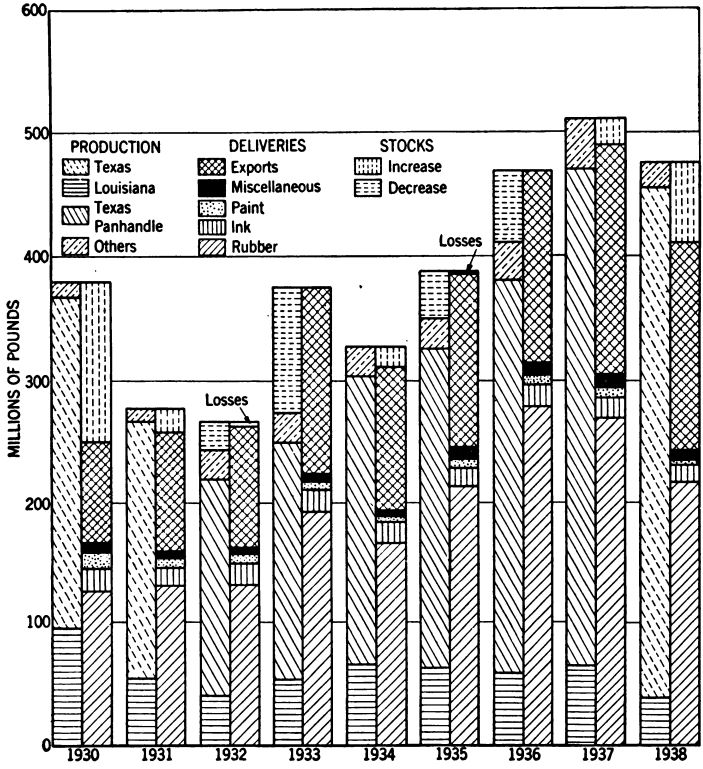

FIGURE 2.—Production and consumption of carbon black, 1930-38.

gain in the relative importance of sales to foreign countries. (See fig. 2.)

*Domestic consumption.*—Domestic sales in 1938 were 20 percent less than in 1937. Reports from producers indicate that domestic sales in 1938 were divided as follows: Rubber companies, 217,231,000 pounds (89 percent); ink companies, 14,131,000 pounds (6 percent); paint companies, 4,229,000 pounds (2 percent); and miscellaneous purposes, 7,883,000 pounds (3 percent). These data indicate chiefly a small increase in the relative importance of sales to rubber companies at the expense of sales for miscellaneous purposes.

According to E. G. Holt, of the Bureau of Foreign and Domestic Commerce, who has again supplied data on rubber consumption, the total consumption of rubber in the United States declined 21 percent in 1938, or from 705,600 long tons in 1937 to 558,800 in 1938. Of the 1938 total, 437,000 long tons was crude rubber, 120,800 reclaimed

Digitized by Google

rubber, and 1,000 synthetic rubber. Thus in 1938, as opposed to 1937, the consumption of reclaimed rubber, in which relatively little carbon black is used, decreased more than that of crude rubber. Furthermore, the consumption of latex, another type of rubber requiring little carbon black, declined relatively more in 1938 than that of crude rubber. According to statistics of the Rubber Manufacturers Association, the reduction in output of casings (from 53,300,000 in 1937 to 40,100,000 in 1938) was relatively greater than that in rubber consumption but may have been partly offset by a further increase in the average quantity of carbon black used per casing. Summarizing, the decline in sales of carbon black to rubber companies in 1938 (20 percent) was less than the decline in rubber consumption partly because relatively more crude rubber was used, possibly because the average size of casings increased, and probably because the rubber companies increased their stocks late in the year.

The apparent consumption of crude rubber in the world was 944,000 long tons, 14 percent less than the revised total of 1,103,600 long tons in 1937. These data indicate a further decline in the relative importance of the United States as a manufacturer of rubber in 1938 but a further strengthening of its paramount position as a supplier of carbon black.

The business recession of 1938 was attended by a marked decline in advertising and newsprint consumption, hence consumption of ink declined materially. According to data supplied by B. M. Frost, of the Bureau of Foreign and Domestic Commerce, the supply of newsprint available for domestic consumption in 1938 was 3,089,100 short tons, or 27 percent below 4,260,700 short tons for 1937. Sales of carbon black to ink companies decreased from 18,116,000 pounds in 1937 to 14,131,000 pounds in 1938. Speculative buying of carbon black by ink manufacturers may have caused this decline (22 percent) to be less than the drop in apparent consumption of newsprint.

Sales of carbon black to paint companies dropped from 6,159,000 pounds in 1937 to 4,229,000 in 1938, or 31 percent. This decrease checks reasonably well information supplied by E. C. Wood, Chemicals Division, Bureau of Foreign and Domestic Commerce, to the effect that paint production in 1938 was probably 20 to 25 percent below that in 1937.

Sales of carbon black for miscellaneous purposes fell sharply in 1938—from 11,503,000 pounds in 1937 to 7,883,000 in 1938. No details are available as to the particular sales or uses that declined. Probably the situation is not as dark as the 1938 figures indicate, as favorable results from research have been rumored.

Losses incurred in handling carbon black, which have been declining in recent years, were transformed into a net gain of 65,000 pounds compared with a loss of 76,000 pounds in 1937.

*Exports and imports.*[1]—Exports of carbon black, after inceasing for 3 successive years, declined in 1938, when about 168,000,000 pounds were shipped abroad compared with about 184,000,000 pounds in 1937. The material increase in exports in 1937 was largely the result of military preparations in the totalitarian countries, particularly Germany. However, the decrease in 1938, being quite generally distributed over all the principal importing countries probably reflected a general slump in activity at rubber plants.

[1] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

Compared with domestic prices foreign quotations held up well; the average export value dropped only 0.21 cent per pound, or from 4.72 cents per pound in 1937 to 4.51 per pound in 1938.

Important gains in exports to foreign countries were notably few in 1938. The outstanding gain of about 40 percent over 1937 was credited to Italy. The United Kingdom continued as the leading foreign customer, with France second and Germany third. Although Germany imported less carbon black from the United States in 1938 than in 1937 it is doubtful if the production of substitutes was responsible. The low prices for carbon black in 1938 were not conducive to the development of substitutes, even in Germany.

An irregular upward trend is noticeable in exports by months for 1938. The highest monthly total, about 18,000,000 pounds, was exported in December and the lowest, about 11,000,000 pounds, in April. Galveston (Houston) further consolidated its position as the leading shipping port in 1938.

Imports of "gas black and carbon black," as reported by the Bureau of Foreign and Domestic Commerce, totaled 390 pounds valued at $30 in 1938 compared with 34 pounds valued at $2 in 1937. Im-

Digitized by Google

ports of acetylene black, a competitor for certain uses, declined from 1,309,144 pounds valued at $139,904 in 1937 to 1,220,781 pounds valued at $127,889 in 1938.

## STOCKS

As usual, the decline in demand proceeded faster than that in production, hence stocks increased. Stocks at the plants rose from 100,497,000 pounds the first of the year to 166,159,000 pounds on December 31. Although the gain in stocks was material and weakened the market, it was much less than the annual gains of 1929 and 1930; furthermore, overproduction was corrected to the extent that stocks actually declined in the last quarter of 1938. However, lest this statement be taken too optimistically it should be remarked that rubber manufacturers probably stocked up late in the year in anticipation of higher prices. On the other hand, stocks in the form of finished rubber goods held by manufacturers declined materially—as stocks of casings decreased from about 10,400,000 on December 31, 1937, to about 8,500,000 on December 31, 1938.

## PRICES AND VALUES

Carbon-black prices in 1938 were distressing to producers; they reached unprecedented lows early in the year and never recovered in spite of greatly increased business in the last half of the year. The Zone A spot price declined on January 10 to less than 3 cents per pound, formerly considered the absolute minimum based on costs. On January 17 the price was cut an additional 0.25 cent (to 2.7 cents). It was raised to 2.75 cents on April 4, but this increase (0.05 cent) simply covered increased freight rates.

The weighted average f. o. b. price at plants fell from 3.41 cents in 1937 to 2.41 cents in 1938. The spread between the average spot price and the average value declined from about 0.90 cent per pound in 1937 to 0.34 cent in 1938.

*Quoted prices on various grades of carbon black, 1937–38, in cents per pound*

# HELIUM

H. S. KENNEDY and C. W. SEIBEL

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Sale by the Bureau of Mines | 1077 | Cliffside gas field | 1079 |
| Uses | 1078 | Amarillo plant | 1079 |

The expectation of wider use of helium has materialized. The act approved September 1, 1937 (50 Stat. 885), authorizes sale by the Bureau of Mines of helium not needed for Government use, upon payment in advance and under regulations approved by the President, for medical, scientific, and commercial use. Regulations were approved by the President on January 14, 1938, and amended with the President's approval on March 10, 1938. As a result of the enactment, helium may be purchased at reasonable prices from the Bureau of Mines, and it is likely that still greater impetus will be given to the use of helium. During the year 1938, the Bureau entered into 20 contracts with private parties for the sale of more than 800,000 cubic feet of helium.

The helium produced at the Bureau of Mines helium plant, Amarillo, Tex., is about 98.2 percent pure. The impurity is largely nitrogen. Under the regulations, the term "contained helium" is used to designate the actual quantity of helium contained in a mixture of that element and other gases. The regulations define the helium sold by the Bureau of Mines as "market helium," and this item is broken down into the specific uses "medical," "scientific," and "commercial." During the last fiscal year one charge was made for helium used for medical and scientific purposes, and a slightly higher charge was made for helium sold for commercial use.

Market helium is sold at approximately the cost of production, with a reasonable charge added to cover items of depreciation and depletion. The Government wishes to make helium available at the lowest reasonable price, and the regulations provide that the helium shall be sold at a price slightly greater than cost. The cost of producing helium varies with the quantity produced; as a result, the exact cost cannot be predetermined, because of the uncertain quantity required by commercial users. Therefore, it is necessary to require deposits in advance of deliveries to protect the Government from possible loss because of increased cost. These deposits are based on estimated charges for the helium itself and an amount to cover services independent of the actual production of helium performed by the Bureau for the purchasers. These service charges include expenses incident to the transportation of cylinders to and from railroad stations, filling cylinders, and repairing them when necessary.

Digitized by Google

The estimated cost for market helium for the fiscal year 1938 was $14.25 per thousand cubic feet. To protect the Government in the event of an unlooked-for advance in cost of production, a deposit of $17.10 was required of each purchaser for medical and scientific helium, and if the helium was to be used for commercial purposes, a deposit of $19.15 per thousand cubic feet was required. Under the terms of the regulations, any difference between the deposit (based on estimated cost) and the charges for helium and services (based on actual cost) is refunded to the purchaser at the end of the fiscal year, when the actual cost has been computed. The cost of production for the fiscal year 1938, as approved by the Secretary of the Interior, was $12.83 per thousand cubic feet, which resulted in a charge of $13.47 for helium used for medical and scientific purposes and of $15.08 for helium used commercially.

Pursuant to the Helium Act, helium is furnished to Government agencies on their requisition and payment of a proportional share of the expenses incident to the administration, operation, and maintenance of the properties. The proportionate share paid by Government agencies for the fiscal year 1938 was $11.16 per thousand cubic feet of helium received.

*Uses.*—The major use for helium still is for inflation of nonrigid airships. Both the Army and Navy have airships or observation balloons using helium, and during the past year Congress authorized the building of a new airship for the Navy Department. Moreover, the Goodyear Tire & Rubber Co. has continued to operate several of its small airships, which led to a contract for 500,000 cubic feet of helium during the year.

The use of larger and larger balloons by the Weather Bureau in determining wind direction and in radio-sonde observations for obtaining data used in weather predictions, has caused the replacement of explosive hydrogen with appreciable quantities of helium. Helium now is being furnished to approximately 120 stations of the Weather Bureau, and about 500,000 cubic feet of helium has been used since July 1, 1938, when helium was substituted for hydrogen. The Weather Bureau has expressed the desire to have all its stations use helium during the next fiscal year, which indicates a demand for approximately 1,500,000 cubic feet.

Before helium could be obtained from the Government, it sold at approximately $150 per thousand cubic feet when purchased in small quantities. Such a price made its use for medical purposes, except for wealthy persons, almost prohibitive. Helium can now be purchased from the Government at about one-tenth that selling price. However, helium by itself is not normally used for medical treatment; it is mixed with approximately 20 percent oxygen. The Government is not prepared to mix oxygen with the helium that it produces, and private individuals must purchase such mixtures from commercial distributors. However, it has been estimated that approximately 200,000 cubic feet of helium sold during the calendar year 1938 was used for medical purposes. This quantity of helium, according to authorities on the subject, is enough to furnish 20,000 patient-hours of treatment. Helium mixed with 20 percent oxygen and breathed by persons afflicted with asthma offers almost immediate relief, according to reports from the medical profession.

Digitized by Google

Recently a mixture of helium and oxygen has been tested with encouraging results in the treatment of sinus and Eustachian tube blockage. Men working in tunnels are subjected to air pressure before entering the tunnel face, and "blocks" occur in the Eustachian tubes if the men have a stoppage in these tubes due to sinus infection or colds. These tubes must be clear to permit the pressure on the outside and inside of the ear to equalize. If the tubes are not clear, severe pain prevents the men from working under pressure.

Approximately 5,000 cubic feet of helium has been delivered to the National Bureau of Standards for certain specific heat determinations. Small quantities have also been supplied to several universities and institutions for scientific research.

In 1925 the Bureau of Mines published Report of Investigations 2670, Possibilities in the Use of Helium-Oxygen Mixtures as a Mitigation of Caisson Disease, by R. R. Sayers, W. P. Yant, and J. H. Hildebrand and issued a press release in 1926 entitled, "Helium Helps the Diver." These reports dealt with research on the possibility of using helium-oxygen mixtures in deep-sea diving. The Navy Department has continued this research, and others are becoming increasingly interested in this subject. Within the past year new deep-sea diving records have been made possible through the use of helium-oxygen mixtures.

*Cliffside gas field.*—The four gas wells on the Government's Cliffside helium reserve produced a total of 361,065,000 cubic feet of helium-bearing natural gas during the fiscal year 1938, making a cumulative production for the field of 5,053,153,000 cubic feet to June 30, 1938.

*Amarillo plant.*—Although the Bureau of Mines Helium Plant continued to operate on intermittent schedule during the fiscal year 1938, the production of helium was almost 27 percent greater than that of 1937. The helium production for the fiscal year 1938 was 6,099,960 cubic feet, which makes a cumulative production of 84,260,165 cubic feet of helium produced in the plant from the beginning of production in April 1929 to June 30, 1938. During the first half of the current fiscal year, an additional 3,906,975 cubic feet of helium was produced, making a total production of 88,167,140 cubic feet of helium to December 31, 1938.

# ASPHALT AND RELATED BITUMENS

By A. H. REDFIELD [1]

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1081 | Manufactured or petroleum asphalt | 1083 |
| Salient statistics | 1081 | Production | 1083 |
| Native asphalts and bitumens | 1082 | Stocks | 1083 |
| Bituminous rock | 1082 | Sales | 1084 |
| Gilsonite and wurtzilite | 1082 | Domestic demand | 1088 |
| Sulfonated bitumen | 1082 | Distribution by rail | 1089 |
| Exports | 1082 | Foreign trade | 1090 |
| | | Road oil | 1091 |

To meet an 8-percent increase in total demand, domestic and foreign, for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) petroleum refineries in the United States increased their output 3 percent from 1937 to 1938 and reduced their inventories 12 percent from December 31, 1937, to December 31, 1938. The entire increase was in domestic demand as exports of petroleum asphalt were 3 percent less in 1938 than in 1937. Imports of lake asphalt, grahamite, and petroleum asphalt dropped sharply; they comprised only 2 percent of the total demand in 1937 and less than 0.75 percent in 1938. Only 5 percent of the petroleum asphalt produced in the United States was sold to foreign countries in 1937 and only 4 percent in 1938.

## NATIVE ASPHALT AND BITUMENS

*Bituminous rock.*—As a result of an apparent increase in the laying of high-type asphaltic pavements sales of bituminous rock by producers increased from 447,213 short tons valued at $2,035,410 in 1937 to 483,497 tons valued at $2,409,616 in 1938. Rock-asphalt operators in Kentucky and Alabama sold 159,276 tons valued at $865,818 in 1937 and 215,142 tons valued at $1,379,138 in 1938. On the other hand, sales by operators in Texas, Oklahoma, and New Mexico decreased from 265,895 tons valued at $1,075,832 in 1937 to 241,299 tons valued at $939,688 in 1938. Sales by producers in California and Kansas were higher in 1938 than in 1937, but sales in Missouri were slightly lower.

*Gilsonite and wurtzilite.*—Sales of gilsonite by producers in northeastern Utah decreased from 38,038 short tons valued at $973,007 in 1937 to 28,574 tons valued at $649,724 in 1938. A 10-percent increase in railroad freight rates and decreased demand for varnishes and printing ink reduced the domestic demand for gilsonite; higher steamship freight rates and exchange difficulties reduced sales of gilsonite in other countries.

Sales of wurtzilite decreased from 133 tons valued at $10,621 in 1937 to 76 tons valued at $5,920 in 1938.

*Sulfonated bitumen.*—In 1938, as in 1937, a small quantity of natural sulfonated bitumen was produced in Box Elder County, Utah, near Ogden.

*Exports.*—A decrease of 35 percent in demand from Europe, especially from France, Germany, and the United Kingdom, caused exports of natural asphalt and bitumen, unmanufactured, to decline from 18,535 short tons valued at $720,358 in 1937 to 13,546 tons valued at $543,509 in 1938. Of the total exports, 75 percent went to Europe both in 1937 and in 1938; 10 percent went to Canada in 1938 compared with 8 percent in 1937; 2 percent went to South America in 1938 compared with 7 percent in 1937; and 9 percent went to Asia, chiefly Japan, in 1938 compared with 7 percent in 1937.

## MANUFACTURED OR PETROLEUM ASPHALT

*Production.*—Petroleum refineries produced 3 percent more asphalt in 1938 than in 1937. The total refinery output in 1938 included 165,440 tons of other petroleum products blended with the asphalt to produce commercial varieties of the required consistency.

Of the 1938 production of petroleum asphalt, 32 percent was made from foreign crude imported chiefly from Venezuela and Mexico compared with 36 percent in 1937. Runs of foreign petroleum to stills increased less than 1 percent—from 25,996,000 barrels in 1937 to 26,187,000 in 1938. However, as the recovery of asphalt from foreign crude decreased from 33 percent of foreign crude runs in 1937 to 30 percent in 1938, the production of asphalt from foreign oil decreased 8 percent—from 1,555,803 tons in 1937 to 1,438,245 in 1938. East Coast refineries manufactured 78 percent of their asphalt from foreign crude in 1938 compared with 81 percent in 1937, and Gulf Coast refineries made 16 percent of their asphalt from foreign crude in 1938 compared with 30 percent in 1937. At the same time the production of asphalt from domestic crude increased (especially in the refining districts west of the Mississippi River and in the Appalachian district, in spite of a decline in the Indiana, Illinois, Kentucky, etc., district) from 2,804,121 tons in 1937 to 3,068,631 in 1938.

*Stocks.*—To meet an increase of 355,543 short tons in the indicated domestic demand (offset to a slight extent by a decline of 6,258 tons in export demand) the petroleum refineries of the United States enlarged their output of asphalt 146,952 tons in 1938, while imports of lake asphalt, grahamite, and petroleum asphalt decreased 57,952 tons. Consequently, stocks of asphalt at refineries were 67,038 tons lower on December 31, 1938, than on December 31, 1937, in contrast with an increase of 193,247 tons during 1937. Decreases in asphalt inventories were general east of the Rocky Mountains but were greatest in the Indiana, Illinois, Kentucky, etc., and Louisiana-Arkansas districts.

| 1937 | 144,467 | 32,162 | 4,031,953 | 42,994,437 |

*Sales.*—Total sales of petroleum asphalt by refineries increased 11 percent in quantity but decreased 4 percent in value from 1937 to 1938. The average value at the refinery of asphalt sold in 1938 was $9.24 per short ton compared with $10.66 in 1937.

Highway construction absorbed more than three-fifths of all asphalt sold in 1938. In general, such statistics as are available indicate an increase in street and road construction in 1938 over 1937. Awards of street and road contracts exceeding $25,000, compiled by the Engineering News-Record, increased 54 percent in value (from $414,537,000 in 1937 to $637,862,000 in 1938)—about 55 percent in volume if allowance is made for a slight decrease in construction costs from 1937 to 1938. The average mileage under construction under the supervision of the Bureau of Public Roads increased from 8,062 in 1937 to 8,140 in 1938. The total mileage of State highways (including Federal-aid roads completed) increased from 30,632 in 1937 to 30,977 in 1938, according to the American Association of State Highway Officials. However, average employment for construction and maintenance of Federal and State highways, as reported to the Bureau of Public Roads, decreased from 281,086 in 1937 to 273,055 in 1938.

[1] DEFINITIONS

*Paving asphalt.*—Refined asphalt and asphaltic cement, fluxed and unfluxed, produced for direct use in the construction of sheet asphalt, asphaltic concrete, asphalt macadam, and asphalt block pavements, and also for use as joint filler, in brick, block, and monolithic pavements.

*Roofing asphalt.*—Asphalt and asphaltic cement used in saturating, coating, and cementing felt or other fabric and in the manufacture of asphalt shingles.

*Waterproofing asphalt.*—Asphalt and asphaltic cement used to waterproof and dampproof tunnels, foundations of buildings, retaining walls, bridges, culverts, etc., and for constructing built-up roofs.

*Briquetting asphalt.*—Asphalt and asphaltic cement used to bind coal dust or coke breeze into briquets.

*Mastic and mastic cake.*—Asphalt and asphaltic cement for laying foot pavements and floors, waterproofing bridges, lining reservoirs and tanks, capable of being poured and smoothed by hand troweling.

*Pipe coatings.*—Asphalt and asphaltic cement used to protect metal pipes from corrosion.

*Molding compounds.*—Asphalts used in the preparation of molded composition, such as battery boxes, electrical fittings, push buttons, knobs, handles, etc.

*Miscellaneous uses.*—Asphalt and asphaltic cement used as dips, and in the manufacture of acid-resisting compounds, putty, saturated building paper, fiber board and floor coverings, and not included in the preceding definitions.

*Flux.*—Liquid asphaltic material used in softening native asphalt or solid petroleum asphalt for paving, roofing, waterproofing, and other purposes.

*Cut-back asphalt.*—Asphalt softened or liquefied by mixing with petroleum distillates.

*Emulsified asphalt and fluxes.*—Asphalts and fluxes emulsified with water for cold-patching, road laying, and other purposes.

*Other liquid products.*—Petroleum asphalt, exclusive of fuel oil used for heating purposes, not included in the preceding definitions.

The increase in mileage of State highways built during 1938 over 1937 was in the higher and intermediate types of surface and in grading and draining operations. Construction of the lighter types of surface declined 7 percent from 1937 to 1938. Asphaltic types (asphaltic concrete, asphaltic macadam, and low-cost bituminous mixtures) gained 22 percent from 1937 to 1938—they constituted 70

Digitized by Google

percent of the mileage of higher and intermediate types laid on State highways in 1937 and 78 percent in 1938. On the other hand, the total mileage of portland-cement concrete and of brick and block pavement declined 21 percent from 1937 to 1938.

No comprehensive statistics are available to show the proportions of the various types of surface laid on city and town streets. Apparently there was a general increase in the yardage of municipal street paving, especially in the larger cities, an important but little-recorded field of demand.

Increases in road and street contracts awarded were general throughout the United States but were greatest in the Pacific States, the States lying between the Rocky Mountain front and the Mississippi River, and the Middle Atlantic States. The greatest increase in construction of asphaltic types of pavement was in low-cost bituminous surfaces—from 6,932 miles in 1937 to 9,077 in 1938. Eighty-five percent of this mileage was laid in the less densely populated States west of the Mississippi River and south of the Ohio and Potomac Rivers. A striking increase in the construction of low-cost bituminous surfaces in Indiana raised the proportion of the States bordering the Great Lakes from 10.5 percent of the National total in 1937 to 21 percent in 1938. Asphaltic-macadam paving construction decreased from 574 miles in 1937 to 487 in 1938. Fifty-one percent was laid east of the Mississippi River in 1937 and 80 percent in 1938. Asphaltic-concrete (including sheet-asphalt and natural-rock-asphalt) pavement construction decreased from 1,291 miles in 1937 to 1,137 in 1938. Of this more expensive type of pavement, 87 percent was laid east of the Mississippi River in 1937 and 67 percent in 1938.

Increased construction of high-type, hard-surfaced streets and highways is indicated by a 9-percent gain in sales of paving asphalt of less than 200 penetration from 1,162,497 short tons in 1937 to 1,271,838 in 1938. Gains in sales in the East Coast district—from 625,652 tons in 1937 to 668,301 in 1938—in the Gulf Coast districts of Texas and Louisiana—from 121,258 tons in 1937 to 139,807 in 1938—and in the Inland districts of Texas and Arkansas and Louisiana—from 79,200 tons in 1937 to 154,879 in 1938—more than offset declines in California—from 209,062 tons in 1937 to 190,063 in 1938—and in the Indiana, Illinois, Kentucky, etc., district—from 80,010 tons in 1937 to 67,384 in 1938.

Sales of paving asphalt made from foreign petroleum decreased from 490,873 tons in 1937 to 477,959 in 1938, and sales of paving asphalt made from domestic crude increased from 671,624 tons in 1937 to 793,879 in 1938.

Sales of paving flux increased from 130,616 tons in 1937 to 193,704 in 1938. The principal gains were in the East Coast district (from 48,437 tons in 1937 to 73,635 in 1938) and in California (from 45,418 tons in 1937 to 61,623 in 1938). Smaller gains were recorded in the Indiana, Illinois, Kentucky, etc., district, in Texas, and in the Louisiana-Arkansas district.

Extensive construction of lighter types of surface, both on State highways and secondary roads, as well as continued use of cut-back asphalts, for soil stabilization and revetments, is indicated by a 27-percent increase in sales from 1,099,498 tons in 1937 to 1,392,997 in 1938. The gains were greater west of the Mississippi River; only the Texas Gulf Coast district furnished an exception to the general increase

Digitized by Google

over the United States. As in 1937, the greatest increase was in the Oklahoma, Kansas, and Missouri district (from 165,916 tons in 1937 to 253,253 in 1938). This district was followed by the Rocky Mountain district (from 100,341 tons in 1937 to 149,448 in 1938); the Indiana, Illinois, Kentucky, etc., district (from 160,695 tons in 1937 to 205,222 in 1938); the East Coast district (from 393,970 tons in 1937 to 434,599 in 1938); and Inland Texas (from 94,419 tons in 1937 to 138,477 in 1938). Of the major districts producing cut-back asphalts, California made the lowest gain—from 105,812 tons in 1937 to 123,428 in 1938.

The greater increase was in sales of rapid-curing cut-backs—from 673,035 tons valued at $7,948,608 in 1937 to 892,910 valued at $9,129,262 in 1938. At the same time sales of medium-curing cut-backs increased in quantity from 426,463 tons in 1937 to 500,087 in 1938 but declined in value from $4,307,229 to $3,828,718.

The upward trend in sales of asphalt emulsions was interrupted in 1938. Petroleum refineries sold 56,654 tons (13,346,799 gallons) valued at $754,437 in 1937 and 56,953 tons (13,417,238 gallons) valued at $678,779 in 1938. In addition, 49,336,367 gallons valued at $4,339,596 were sold in 1937 and 43,928,186 gallons valued at $3,659,258 in 1938 by six major industrial companies that purchased asphalt from petroleum refineries. Accordingly, total known sales of emulsified asphalts and fluxes decreased in quantity from 62,683,166 gallons in 1937 to 57,345,424 in 1938 and in value from $5,094,033 in 1937 to $4,338,037 in 1938.

Roofing manufacture furnished the second-largest demand for asphalt, absorbing 27 percent of the total sales in 1937 and 25 percent in 1938. A 16-percent rise in shipments of prepared roofing and asphalt siding reported by the Bureau of the Census—from a total of 30,461,447 squares in 1937 to 35,238,029 in 1938—was reflected in a 3-percent rise in sales of roofing asphalt and roofing flux combined—from 1,091,202 tons in 1937 to 1,127,635 in 1938. The principal gains occurred west of the Mississippi River. Texas refineries increased their sales of roofing asphalt and roofing flux from 46,894 tons in 1937 to 92,885 in 1938. Refineries of Louisiana and Arkansas sold 122,290 tons of roofing asphalt and roofing flux combined in 1937 and 132,715 in 1938. In the Oklahoma, Kansas, and Missouri district sales of roofing asphalt and flux increased from 40,328 tons in 1937 to 65,345 in 1938. In California the gain was smaller—from 75,224 tons in 1937 to 77,998 in 1938. On the other hand, refineries of the Indiana, Illinois, Kentucky, etc., district decreased their sales of roofing asphalt and flux from 309,870 tons in 1937 to 289,809 in 1938 and East Coast refineries from 460,984 tons in 1937 to 421,128 in 1938.

A 3-percent decline in the total floor space of both residential and nonresidential contracts awarded, as estimated by the F. W. Dodge Corporation for 37 States, was accentuated in sales of waterproofing asphalt and flux, which decreased from 115,681 tons in 1937 to 71,950 in 1938.

In response to a 13-percent drop in the manufacture of coal briquets, sales of briquetting asphalt fell 9 percent—from 63,767 tons in 1937 to 57,741 in 1938.

The decrease of 11 percent in sales of asphalt for blending with rubber—from 26,713 tons in 1937 to 23,814 in 1938—may be attributed chiefly to a 24-percent decline in the demand for rubber from 1937 to 1938.

Digitized by Google

## DOMESTIC DEMAND

The indicated domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) was 9 percent greater in 1938 than in 1937, increasing from 337,442 short tons per month in 1937 to 367,070 in 1938.

In terms of the long-time trend the indicated demand was 23 percent above the expected demand for 1938, whereas it was 17 percent above the expected demand for 1937; that is, if the national demand had continued the average rate of growth it manifested from 1908 to 1936 it would have averaged 289,136 tons a month in 1937 and 297,864 in 1938. If these averages are used as a standard of comparison, the indicated demand of 337,442 tons a month in 1937 was 117 percent of the expected demand (289,136 tons), and the indicated demand of 367,070 tons a month in 1938 was 123 percent of the expected demand (297,864 tons).

The demand for asphalt is seasonal to a marked degree, reaching its maximum in August and its minimum in February. Normally, 65 percent of the indicated consumption of asphalt occurs in the 6 months from May 1 to October 1; from 1936 to 1938, 69 percent of the annual total apparently was consumed in these months. Consequently, to furnish an adequate standard of comparison the monthly trend values are multiplied by a "seasonal factor" for each month.

In the first quarter of 1938 the indicated demand averaged 118 percent of the long-time trend multiplied by seasonal factors compared with 105 percent in the first 3 months of 1937. In the second quarter of 1938 it declined to 116 percent of the expected demand for these months compared with 119 percent during the second quarter of 1937. From July to September 1938 the demand was highest, averaging 133 percent of the expected demand compared with 132 percent in the same months of 1937. In the last quarter of 1938 the indicated demand averaged 122 percent of the expected demand compared with 99.7 percent in the last 3 months of 1937.

*Relation of indicated asphalt demand to basic trend multiplied by seasonal factors, 1937–38*

| Month | 1937 | | | 1938 | | |

## DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States decreased from 4,337,548 short tons in 1937 to 4,295,232 in 1938, according to freight-commodity statistics compiled by the Interstate Commerce Commission. The principal decreases occurred east of the Mississippi River and Lake Michigan and north of the Ohio and Potomac Rivers; in general, more asphalt was terminated by class I railroads west of the Mississippi River and south of the Ohio and Potomac Rivers in 1938 than in 1937.

Forty-nine percent of the asphalt (petroleum, lake, and natural-rock) terminated in the continental United States by land carriers and intraport vessels was delivered to consumers in the Northeastern district, lying north of the Potomac and Ohio Rivers and east of the Mississippi and Illinois Rivers. Railroads and minor carriers terminated 2,400,706 short tons of asphalt in this district in 1937 and 2,418,722 tons in 1938. In the Southeastern district, lying south of the Potomac and Ohio Rivers and east of the Mississippi and Pearl Rivers, land deliveries of asphalt increased from 531,230 tons in 1937 to 663,802 tons in 1938. In the Southwestern district, lying west of the Mississippi and Pearl Rivers and south of St. Louis, Kansas City, and Amarillo, asphalt deliveries by rail and truck increased from 339,443 tons in 1937 to 372,610 tons in 1938. In the North Central district, lying between the Great Lakes and the Rocky Mountain front, 632,554 tons were delivered in 1937 and 677,478 tons in 1938. In the Pacific-Rocky Mountain district, lying west of Great Falls, Cheyenne, Denver, Albuquerque, and El Paso, the tonnage of asphalt terminated increased from 612,230 tons in 1937 to 768,773 in 1938.

## FOREIGN TRADE

*Imports.*—Imports of natural asphalt and bitumen into the United States declined from 28,663 short tons valued at $395,882 in 1937 to 23,645 valued at $378,209 in 1938. Imports of lake asphalt from Trinidad decreased from 24,790 tons valued at $239,697 in 1937 to 19,396 valued at $205,038 in 1938. On the other hand, imports of grahamite from Cuba rose from 3,162 tons valued at $52,024 in 1937 to 3,826 valued at $65,344 in 1938.

Atlantic coast ports (chiefly New York) received 16,320 tons of natural asphalt and bitumen and Gulf coast ports (Mobile, New Orleans, and Galveston) 7,204 tons in 1938.

Imports of petroleum asphalt, including cut-backs, and road oil decreased from 344,960 barrels (62,720 short tons) valued at $260,132 in 1937 to 53,822 barrels (9,786 tons) valued at $38,883 in 1938. Of the 1938 imports, 53,449 barrels received in the customs district of Philadelphia came from Mexico and 373 barrels received in the customs district of Puerto Rico came from the Netherlands.

*Exports.*—Resuming the downward trend manifested since 1928, exports of petroleum asphalt were 3 percent smaller in 1938 than in 1937. Although foreign sales of unmanufactured petroleum asphalt increased from 41,299 short tons valued at $657,894 in 1937 to 42,290 valued at $734,683 in 1938, sales of manufactures of petroleum asphalt to other countries decreased from 167,458 tons valued at $2,453,233 in 1937 to 160,209 valued at $2,295,479 in 1938. As most of these manufactures were simply processed forms of asphalt, the exports of manufactured and unmanufactured asphalt in 1937 and 1938 have been combined in the following table for comparison with the 1936 exports that were not so differentiated.

The principal decreases were in sales to eastern and southern Asia, especially China, Japan, British Malaya, British India, and Ceylon. On the other hand, more asphalt was sold to Australia, New Zealand, and French Indochina. Less asphalt was shipped from the United States to the Union of South Africa and Mozambique in 1938 than in 1937. However, the decreases in exports of asphalt to eastern Asia and the Indian Ocean region were partly compensated by increases in sales to other countries of North America, to South America, and to the United Kingdom.

## ROAD OIL

Decreased construction of oil-treated macadam, gravel, and sand-clay highways resulted in a decline of 9 percent in refinery sales of road oil—from 8,733,650 barrels in 1937 to 7,904,890 in 1938. As a result of lower prices, the value at the refineries of sales of road oil decreased 20 percent—from $12,183,213 in 1937 to $9,704,689 in 1938.

The declines were greatest in the following districts: California, Arkansas and Louisiana Inland; Indiana, Illinois, Kentucky, etc.; Rocky Mountain; and East Coast. Gains in the Oklahoma, Kansas, and Missouri district, the Appalachian district, and the Louisiana Gulf Coast district were insufficient to offset the general decline.

Of the road oil sold in 1938 only 632,423 barrels valued at $1,080,699 were made from foreign petroleum, imported chiefly from Venezuela and Mexico. Of the road oil made from foreign crude, 77 percent was sold by refineries of the Atlantic Coast district in 1937 and 76 percent in 1938; the remainder was sold by Gulf Coast refineries of Louisiana and Texas.

| Louisiana-Arkansas: | | | | |
| Louisiana Gulf Coast | 133,922 | 182,502 | 176,476 | 264,355 |
| Arkansas and Louisiana Inland | 395,171 | 457,024 | 129,828 | 170,048 |
| Total, Louisiana-Arkansas | 529,093 | 639,526 | 306,304 | 434,403 |
| Rocky Mountain | 1,245,266 | 2,494,609 | 1,183,880 | 1,492,280 |
| California | 2,998,198 | 3,161,355 | 2,413,311 | 2,453,810 |
| Grand total | 8,733,650 | 12,183,213 | 7,904,890 | 9,704,689 |

Petroleum refineries in the United States reported the production of 7,542,755 barrels of road oil in 1938 compared with 8,087,231 in 1937. The refinery output of road oil in 1938 was augmented by 722,100 barrels of other petroleum products, chiefly fuel oil, transferred to road-oil stocks compared with 1,089,167 barrels similarly transferred in 1937. Stocks of road oil and transferred oils held at refineries decreased 44,296 barrels during 1938, whereas they increased 127,804 barrels during 1937. Consumption of road oil at refineries in operations, transfers, losses, and adjustments were 404,261 barrels in 1938 compared with 314,944 in 1937.

The average value of road oil sold in the United States f. o. b. refinery fell from $1.39 in 1937 to $1.23 in 1938. The principal decreases were in the Appalachian district (from $2.12 per barrel in 1937 to $1.27 in 1938), in the Rocky Mountain district (from $2.00 to $1.26), in the Oklahoma, Kansas, and Missouri district (from $1.18 to $0.92), in the Indiana, Illinois, Kentucky, etc., district (from $1.47 to $1.36), and in the Texas Gulf Coast district (from $1.68 to $1.50). Gains in Inland Texas (from $1.21 to $1.27), in the Gulf Coast of Louisiana (from $1.36 to $1.50), and in Arkansas and Louisiana Inland ($1.16 to $1.31) were insufficient to check the general decline.

Production of portland cement in the United States in 1938 declined to 105,357,000 barrels and shipments to 106,324,127 barrels valued at $153,977,226, according to final annual reports submitted by cement companies to the Bureau of Mines. The preliminary figures on production and shipments for 1938, published by the Bureau of Mines in January 1939, were each 0.2 percent greater than the final figures. The final figures represent a decline of 9 percent in production, 7 percent in shipments, and 9 percent in mill value of shipments compared with 1937. For the first 5 months of 1938 shipments were 13 percent lower than for the same period of 1937. Thereafter the decline from the corresponding months of 1937 was smaller, but not until October did shipments in 1938 exceed those in 1937.

The Federal Reserve Board annual index for cement production in 1938 was 71 compared with 65 for the durable-goods industries and 64 for the construction industries. Corresponding figures for 1937 were cement 78, durable-goods industries 109, and construction industries 59.

The average factory value was $1.45 a barrel in 1938 compared with $1.48 a barrel in 1937.

Shipments included 3,385,523 barrels of high-early-strength portland cement valued at $6,247,699, an average of $1.85 a barrel, in 1938 compared with 3,845,314 barrels valued at $7,134,468, an average of $1.86 a barrel, in 1937.

The quantity of natural, masonry (natural), and puzzolan cements produced decreased 10 percent and shipments 7 percent compared with 1937. The value of shipments of these varieties declined 1 percent.

The following tables present the outstanding features of the cement industry during recent years.

## PORTLAND CEMENT

### PRODUCTION, SHIPMENTS, AND STOCKS

Portland cement is the product that is obtained by pulverizing to a fine consistency a clinker produced by calcining to incipient fusion an intimate mixture of properly proportioned argillaceous and calcareous substances, with only such additions subsequent to calcining as may be necessary to control setting and certain other properties. Such additions, which usually comprise about 3 to 3½ percent by weight of the calcined product, consist principally of gypsum or mixtures of gypsum and anhydrite. The principal combinations of raw materials are (1) limestone with clay or shale, (2) cement rock (argillaceous limestone) either alone or with high-calcium limestone, (3) blast-furnace slag and limestone, (4) marl and clay, and (5) oyster shells and clay.

Some years ago all portland cement had fairly constant and uniform properties; in other words, there was only one standard portland cement. In recent years the varied demands of construction have led to the development of a variety of portland cements each adapted to a particular use. These include high-early-strength, masonry, low-heat, and oil-well cements. Statistics for all varieties are given in the general tables covering portland cement, and the special types are discussed in more detail, with statistics wherever available, in a later section of this report. The special portland cements are to be distinguished from certain other types, such as natural and slag-lime cements, which are quite distinct from portland cement and are covered in a separate section of this chapter.

The following tables present the principal statistics of portland cement. In the first table, relating to production, shipments, and stocks by States and districts, the term "active plant" is applied to a mill or group of mills situated at one place and operated by one company. If a company has establishments at different places, its mill or group of mills at each place is counted as a plant. The districts are groups of States related geographically and commercially.

The tables giving data by months, compiled from monthly reports of the producers, include figures of clinker or unground cement produced and in reserve at the mills awaiting manufacture into finished cement. Although the figures may differ slightly from those based on annual reports of the producers, they reflect accurately the seasonal fluctuations in the industry.

Producers' stocks of portland cement reported on hand at the mills were 4 percent lower at the end of 1938 than at the end of 1937. The following table gives stocks on December 31 and the seasonal fluctuations in stocks from 1934 to 1938.

*Producers' stocks of finished portland cement and clinker (unground cement) on hand at mills in the United States on Dec. 31 and monthly range, 1934–38*

| | | Dec. 31 (barrels) | Monthly range | | | |
|---|---|---|---|---|---|---|
| | | | Low | | High | |
| | | | Month | Barrels | Month | Barrels |
| 1934 | Cement | 21,440,594 | January | 19,547,000 | July | 21,852,000 |
| | Clinker | 6,166,000 | do | 5,919,000 | do | 6,588,000 |
| 1935 | Cement | 23,064,563 | October | 20,501,000 | do | 23,287,000 |

## DOMESTIC CONSUMPTION

Apparent consumption (shipments plus imports minus exports) for a series of years is indicated in the table of salient statistics. The only available gage of consumption by States is the record of shipments into States by manufacturers; it is therefore merely approximate. Cement shipped to destinations within a State in which it is manufactured is of course added to that shipped from other States. Shipments into a State during any 1 year may not equal the consumption during that year but over a series of years should afford a fair index of consumption. The following table shows shipments into States in 1937 and 1938 and per capita consumption in each State.

The official figures for exports of cement differ from those reported by manufacturers in the following table, because cement forwarded from mills and destined to foreign countries and to Alaska, Hawaii, and Puerto Rico is reported by shippers as exported, whether or not it leaves the country during the calendar year, whereas the export figures of the Bureau of Foreign and Domestic Commerce record the cement that actually leaves the country during the period specified. The exports recorded by the Bureau of Foreign and Domestic Commerce include all hydraulic cement exported, whereas the figures supplied by producers relate to portland cement only.

The per capita consumption indicated in the table falls short of the total apparent consumption by the quantity of imports, which slightly affect certain States near the Canadian border and the seaboard.

Digitized by Google

The Bureau of Mines has no facilities for collecting statistics on the consumption of portland cement by uses. The following estimates were made by engineers of the Portland Cement Association, who are in touch with various industries throughout the country that use cement.

*Estimated distribution of portland cement in the United States in 1937, by uses*[1]

| Classification | Percent | Barrels |
|---|---|---|
| Paving: Roads, streets, and airports | 23 | 25,940,000 |
| Structural: Buildings, bridges, and railroads | 32 | 36,090,000 |
| Conservation: Reclamation, water supply, and sewerage | 19 | 21,430,000 |
| Housing and miscellaneous uses | 17 | 18,040,000 |
| Farm | 9 | 11,280,000 |
| | 100 | 112,780,000 |

[1] Compiled by the Portland Cement Association; based on analyses of construction figures and other data.

## LOCAL SUPPLIES

The following table compares the shipments from mills within a State or group of States with the estimated consumption (State receipts of mill shipments) and indicates the surplus or deficiency in the supply of cement locally available. Consumption in the States that do not produce cement is also indicated in the table showing consumption per capita.

The surplus in the following table was distributed by years as follows: In 1937, to non-cement-producing States 11,726,959 barrels, foreign countries and Alaska, Hawaii, and Puerto Rico 1,022,454 barrels, and unspecified 51,483 barrels; in 1938, to non-cement-producing States 11,947,543 barrels, foreign countries and Alaska, Hawaii, and Puerto Rico 1,281,298 barrels, and unspecified, 18,539 barrels.

*Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1937–38, in barrels*

## PRICES

The average selling price of portland cement, f. o. b. factories (excluding the price of containers and cash discounts), as reported to the Bureau of Mines, is stated in the table of shipments by States and districts during 1937 and 1938, on a preceding page. The average factory value of portland cement may be higher in certain States than it would be if ordinary structural cement were the only kind considered. For these States the average includes certain special cements that command higher prices, including the white portland cement made in California and Pennsylvania and the high-early-strength portland cement now manufactured in many States. The average selling price per barrel, f. o. b. factory, of white portland cement in 1938 was $3.66; in 1937, $3.77. The average factory selling price of high-early-strength portland cement was $1.85 per barrel in 1938 and $1.86 per barrel in 1937. The sales value of other hydraulic cements is given later in this chapter.

The following table shows the average factory value of portland cement from 1934 through 1938.

*Average factory value per barrel in bulk of portland cement in the United States, 1934–38*

| | | | |
|---|---|---|---|
| 1934 | $1.54 | 1937 | $1.48 |
| 1935 | 1.51 | 1938 | 1.45 |
| 1936 | 1.51 | | |

## CAPACITY

At the end of 1938, the capacity for producing finished portland cement of the 151 plants active and shipping in 1938 and the 11 plants inactive in 1938 but producing or shipping from stock on hand within the 7 previous years is shown in the following table with similar figures for 1937. Figures for plant capacity are based on manufacturers' reports, supplemented by a few estimates.

*Portland-cement manufacturing capacity of the United States, 1937–38, by commercial districts*

| District | Estimated capacity (barrels) | | Percent of capacity utilized | |
|---|---|---|---|---|
| | 1937 | 1938 | 1937 | 1938 |
| Eastern Pennsylvania, New Jersey, and Maryland | 50,712,000 | 50,712,000 | 41.8 | 39.2 |
| New York and Maine | 17,199,000 | 17,124,000 | 37.0 | 36.5 |
| Ohio, western Pennsylvania, and West Virginia | 28,677,000 | 28,447,000 | 37.6 | 33.0 |
| Michigan | 16,605,000 | 16,605,000 | 49.3 | 43.1 |
| Wisconsin, Illinois, Indiana, and Kentucky | 29,046,000 | 29,046,000 | 43.9 | 34.2 |
| Virginia, Tennessee, Alabama, Georgia, Florida, and Louisiana | 25,855,000 | 25,755,000 | 42.6 | 46.7 |
| Eastern Missouri, Iowa, Minnesota, and South Dakota | 23,017,000 | 22,917,000 | 46.4 | 43.6 |
| Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas | 17,159,000 | 17,159,000 | 50.4 | 44.3 |
| Texas | 11,742,000 | 12,042,000 | 58.8 | 57.7 |
| Colorado, Montana, Utah, Wyoming, and Idaho | 6,125,000 | 6,125,000 | 49.9 | 43.9 |
| California | 22,241,000 | 22,820,000 | 53.7 | 46.1 |
| Oregon and Washington | 6,845,000 | 6,945,000 | 67.6 | 42.9 |
| | 255,223,000 | 255,697,000 | 45.5 | 41.2 |

The following estimates, based on the monthly reports of producers, of the relation between the production of finished portland cement and the manufacturing capacity of the industry for each month in1937 and 1938 and for the 12 months ended with each month indicate the seasonal changes in capacity utilized.

The following table gives statistics of capacity, 1936–38, by the two general methods—the "wet" and the "dry"—used in manufacturing portland cement at plants in the United States:

*Portland-cement manufacturing capacity of the United States, 1936–38, by processes*

| Process | Estimated capacity | | | | | | Percent of capacity utilized | | | Percent of total finished cement produced | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Thousands of barrels | | | Percent of total | | | | | | | | |
| | 1936 | 1937 | 1938 | 1936 | 1937 | 1938 | 1936 | 1937 | 1938 | 1936 | 1937 | 1938 |
| Wet | 122,727 | 122,638 | 119,776 | 48.0 | 48.1 | 46.8 | 46.3 | 49.2 | 46.1 | 50.5 | 51.9 | 52.4 |
| Dry | 132,777 | 132,585 | 135,921 | 52.0 | 51.9 | 53.2 | 42.0 | 42.1 | 36.9 | 49.5 | 48.1 | 47.6 |
| | 255,504 | 255,223 | 255,697 | 100.0 | 100.0 | 100.0 | 44.1 | 45.5 | 41.2 | 100.0 | 100.0 | 100.0 |

## RAW MATERIALS

In 1938 producers reported that approximately 32,234,000 short tons of raw materials (exclusive of fuels and explosives) entered into the manufacture of 105,357,000 barrels (19,807,116 short tons) of portland cement in the United States, an average of about 612 pounds to a barrel of finished cement (376 pounds).

The totals were as follows: 26,183,000 tons of limestone and cement rock, 3,054,000 tons of clay and shale (including kaolin for the manufacture of white cement), 428,000 tons of blast-furnace slag, 618,000 tons of marl, 93,000 tons of iron ore, 663,000 tons of gypsum, and 1,195,000 tons of other materials, such as oystershells, sandstone, sand (including glass and silica sand), cinders, fluorspar, diatomite, diatomaceous shale, fuller's earth, bentonite, silica, quartz, ashes, pyrite ore, and pyrite cinder. In cements like the puzzolan portlands, which require highly siliceous materials in their manufacture, the use of a wider variety of materials, such as diatomite, diatomaceous earth and shale, pumicite, and tufa, is being reported.

*Gypsum and anhydrite.*—About 3 percent by weight of gypsum (or gypsum and anhydrite mixtures) is added to the cement clinker at the time of grinding to retard the time of setting. Data [1] on the uses of gypsum show that 674,062 short tons of gypsum and anhydrite were used as cement retarder in 1938. This represented 19 percent of the total crude-gypsum supply (domestic and imported) of the country.

[1] Details in the chapter on Gypsum in this volume.

## MANUFACTURING CONDITIONS AND NEW DEVELOPMENTS

*Plants.*—In 1938 portland cement was manufactured at 149 plants, and shipments were made from 151 plants compared with 149 plants producing and 150 plants shipping in 1937. The new plant of the Gulf Portland Cement Co. at Houston, Tex., began production early in 1938. The new wet-process plant of the Puerto Rico Cement Corporation near San Juan, Puerto Rico, was virtually completed in May 1938, but operation was not reported until January 1939.

Large modernization programs affecting many plants have been reported. A device known as the "electric ear" for controlling the feed of grinding mills has been installed at the Medusa Portland Cement Co. plants at Toledo, Ohio, and York, Pa., and at the Hagerstown (Md.) plant of the North American Cement Corporation. This and many other new developments involving changes from wet to dry process, introduction of Diesel-driven automotive haulage, use of dust-precipitating equipment, and improvements in grinding and calcining have been described in some detail in the technical press.[2]

The use of iron oxide in the cement raw mix is increasing. Single mills in Pennsylvania are using as much as 2,000 tons a year. They employ the lowest-priced material available—roll scale, pyrite cinder, or impure iron ore.

*Specifications.*[3]—The Federal Specifications Executive Committee has been active in issuing specifications on cement. The following have been promulgated: Portland cement, SS–C–191A; high-early-strength, SS–C–201; moderate-heat, SS–C–206; sulfate-resisting, SS–C–211; cements, hydraulic, general specifications (methods for sampling, inspection, and testing), SS–C–158; cement, portland, pozzolana, SS–C–208; and cement, masonry, SS–C–181B. The American Society for Testing Materials has issued a revised tentative specification for masonry cement (C91–T).

The measurement of fineness by surface area of the particles rather than by screen test is now regarded as standard procedure. The Federal specifications mentioned in the preceding paragraph designate the fineness requirement in square centimeters per gram as determined by a Wagner turbidimeter.

*Flotation methods.*—For several years froth flotation has been used successfully at Valley Forge, Pa., for the purification of cement raw materials. A second plant using the process is situated in the Union of South Africa, and recently a third plant has been established at Parma, Argentina. Research on flotation of limestone is now being conducted in the Lehigh Valley cement district of Pennsylvania.

*Fuels.*—According to monthly reports of producers, supplemented by a few estimates by the Bureau of Mines, the following quantities of fuel were consumed at portland-cement plants in the United States in 1938 compared with the production of 104,117,000 barrels of clinker (unground cement) and 105,357,000 barrels of finished cement: Coal, 4,482,663 short tons; oil, 1,927,584 barrels (42 gallons); and natural gas, 37,336,231,988 cubic feet. Corresponding figures for 1937 are:

[2] *See* Pit and Quarry, vol. 31, January 1939, pp. 84–90; Rock Products, vol. 42, February 1939, pp. 31–36, and vol. 42, March 1939, pp. 26–31; Chem. and Met. Eng., vol. 46, March 1939, p. 170.

[3] Copies of Federal specifications may be obtained upon application accompanied by money order, coupon, or cash to the Superintendent of Documents, Government Printing Office, Washington, D. C. Price, 5 cents each. American Society for Testing Materials specifications may be obtained from the office of the secretary of the society, 260 South Broad St., Philadelphia, Pa.

Digitized by Google

Clinker produced, 116,843,000 barrels; and finished cement produced, 116,174,708 barrels. Fuels consumed were: Coal, 5,246,537 short tons; oil, 2,398,130 barrels; and natural gas, 40,449,920,245 cubic feet.

*Electric power.*—The accompanying table gives the electric energy produced at portland-cement plants and that purchased from power companies during 1937 and 1938. The table shows that the industry generated 51 percent of the electric power used at manufacturing plants in 1938.

*Electrical energy used at portland-cement producing plants, 1937–38, by processes, in kilowatt-hours*

| Process | Electrical energy used | | | | | | Finished cement produced | Average electrical energy used per barrel of cement produced |
|---|---|---|---|---|---|---|---|---|
| | Generated at portland-cement plants | | Purchased | | Total | | | |
| | Active plants | Kilowatt-hours | Active plants | Kilowatt-hours | Kilowatt-hours | Percent | Barrels | Kilowatt-hours |
| 1937 | | | | | | | | |
| Wet | 34 | 590,184,860 | 71 | 784,662,991 | 1,374,847,851 | 51.2 | 60,334,050 | 22.8 |
| Dry | 37 | 834,243,065 | 51 | 477,552,518 | 1,311,795,583 | 48.8 | 55,840,658 | 23.5 |

| Percent of total electrical energy used | | 51.0 | | 49.0 | 100.0 | | | |

## SPECIAL PORTLAND CEMENTS

Regular or standard portland cements have been greatly improved during recent years. They attain adequate strength for ordinary use in a much shorter time and have higher ultimate strength and better workability than cements made some years ago. Although these cements are well adapted for all ordinary uses, new conditions have arisen in industry that demand cements having special qualities such as high early strength, unusual plasticity, low or moderate heat of setting, or high resistance to chemical action. Special types of portland cement are discussed in the following paragraphs.

*White portland cement.*—White cement has been manufactured for many years in Pennsylvania and since 1932 in California. It is simply a standard cement, the raw materials of which are unusually pure and which has a very low iron content. To avoid contamination and discoloration from fuel these cements are calcined with gas. They are produced at so few plants that the Bureau is not at liberty to publish figures of production separately.

*Alumina cement.*—A product known as alumina or high-alumina cement was first manufactured in France under the name "ciment fondu." Modifications of alumina cement have been made in the

Digitized by Google

United States for many years under patent. The raw materials are bauxite and limestone or lime, which are completely fused in a furnace. The melted product is cooled rapidly and ground to a fine powder. Production figures cannot be published separately.

*High-early-strength cement.*—For street work where traffic is heavy, construction work where one step must follow another rapidly, and similar uses, a cement that attains adequate strength in 24 hours or less is much in demand. This has led to the development of special high-early-strength cements that are now manufactured in many States.

*Masonry cement.*—Cements suitable for masonry must be plastic and of low shrinkage.

In addition to "masonry portland" and "masonry natural" (discussed on a following page) producers also report masonry cements, hydraulic but not portland, which evidently are specially prepared from portland-cement clinker and other ingredients. Production of such cements, made at 32 plants in 1938, totaled 1,246,263 barrels and shipments 1,225,960 barrels valued at $1,589,908, an average of $1.30 a barrel. Corresponding data for 1937, representing the output of 20 plants, are: Production 747,678 barrels and shipments 694,389 barrels valued at $970,446, an average of $1.40 a barrel. To avoid duplication the above figures are not included in the portland-cement totals, because portland-cement clinker is evidently the principal constituent used.

*Low and moderate heat-of-hardening portland cement.*—Because of the enormous masses of concrete used in large dams such as those in the Tennessee Valley and the Far West a demand has arisen for cements that develop little heat in the process of setting. They include Tennessee Valley Authority type B and other cements that must conform with Federal specifications recorded earlier in this chapter.

*Portland-puzzolan cement.*—Portland-puzzolan cements, including those reported as "high-silica," are specially adapted for resistance to chemical attack such as the reaction with salts contained in sea water. They are made by adding to portland cement, pumicite, slag, or other materials that react with the calcium content of the cement.

*Oil-well cement.*—In the oil-producing States, particularly California, Texas, and Wyoming, special types of portland cement have been developed that are suitable for grouting wells.

*Miscellaneous.*—Other special portland cements include those suitable for resisting high temperatures.

The following table presents statistical data for recent years insofar as they are available. All figures given in this table except those for masonry cement are included in the general tables appearing earlier in this chapter.

*Special portland cements produced and shipped in the United States, 1936–38, by kinds*

| Kind and year | Active plants | Production (barrels) | Shipments | | |
|---|---|---|---|---|---|
| | | | Barrels | Value | |
| | | | | Total | Average |
| High-early-strength: | | | | | |
| 1936 | 52 | 2,982,748 | 3,080,849 | $5,904,399 | $1.92 |
| 1937 | 64 | 4,192,959 | 3,845,314 | 7,134,468 | 1.86 |
| 1938 | 72 | 3,340,582 | 3,385,523 | 6,247,699 | 1.85 |
| Masonry or mortar: | | | | | |
| 1936 [1] | 15 | 430,785 | 404,672 | 518,482 | 1.28 |
| 1937 | 10 | 257,385 | 273,144 | 362,807 | 1.33 |
| 1938 | 5 | 84,875 | 88,905 | 124,239 | 1.40 |
| Low and moderate heat: | | | | | |
| 1936 | 28 | 3,660,380 | 3,600,776 | 4,896,786 | 1.36 |
| 1937 | 29 | 3,169,593 | 3,511,674 | 5,008,217 | 1.43 |
| 1938 | 40 | 4,132,237 | 3,730,814 | 5,550,369 | 1.49 |
| Portland-puzzolan: | | | | | |
| 1936 | 8 | 548,207 | 540,788 | 561,942 | 1.04 |
| 1937 | 6 | 260,194 | 294,384 | 417,130 | 1.42 |
| 1938 | 6 | 159,745 | 149,142 | 229,441 | 1.54 |
| Oil well: | | | | | |
| 1936 | 8 | 250,688 | 237,709 | 508,848 | 2.14 |
| 1937 | 9 | 342,316 | 313,064 | 652,960 | 2.09 |
| 1938 | 7 | 226,769 | 220,122 | 457,665 | 2.08 |
| Miscellaneous: | | | | | |
| 1936 | 18 | 1,232,117 | 1,215,938 | 1,747,802 | 1.44 |
| 1937 | 13 | 580,705 | 587,718 | 928,856 | 1.58 |
| 1938 | 16 | 608,777 | 589,663 | 965,970 | 1.64 |

[1] Figures for 1936 not exactly comparable with succeeding years, as they include some masonry cement other than portland for which separate statistics were not compiled prior to 1937.

## NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

The term "masonry cement" is used here to designate certain cements made by calcining argillaceous limestone at a comparatively low temperature and grinding the calcined material to a fine powder. This product is known as "natural" cement. Portland cements that are also used for masonry are discussed under the special portland cements on a previous page.

In addition to portland-puzzolan cements discussed on a previous page, another type known as slag-lime cement is now made at Birmingham and Graystone, Ala., by mixing granulated blast-furnace slag with hydrated lime and grinding them to a fine consistency. The mixture is not subsequently calcined. The Birmingham industry has been described by Cudworth and Mead.[4]

Figures for production and shipments of special types of cement other than portland are presented in the following table.

[4] Cudworth, James R., and Mead, Joseph C., Utilization of Slag in the Birmingham District, Alabama: Am. Inst. Min. and Met. Eng. Tech. Pub. 796, 1937, 9 pp.

*Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1934–38*

| Year | Production | | Shipments | | Stock (Dec. 31) |
|---|---|---|---|---|---|
| | Active plants | Barrels (376 pounds) | Barrels (376 pounds) | Value | Barrels (376 pounds) |
| 1934 | 14 | 671,588 | 678,204 | $960,732 | 175,865 |
| 1935 | 13 | 1,006,064 | 1,011,411 | 1,437,542 | 172,572 |
| 1936 | 13 | 1,819,488 | 1,760,993 | 2,362,396 | 230,788 |
| 1937 | 12 | 1,900,643 | 1,873,400 | 2,578,885 | 258,031 |
| 1938 | 11 | 1,704,662 | 1,745,541 | 2,558,077 | 196,649 |

## FOREIGN TRADE [5]

*Imports.*—The figures in the following table cover imports of hydraulic cements of all kinds. The values assigned are supposed to represent values in the foreign countries from which the materials are exported, including the cost of containers or coverings. Values ranged in 1938 from $0.93 per barrel for imports from Yugoslavia to $2.02 per barrel for imports from the United Kingdom.

*Hydraulic cement imported for consumption in the United States, 1934–38*

| Year | Barrels | Value | Year | Barrels | Value |
|---|---|---|---|---|---|
| 1934 | 265,997 | $264,416 | 1937 | 1,803,932 | $1,392,633 |
| 1935 | 619,404 | 615,866 | 1938 | 1,727,411 | 1,436,730 |
| 1936 | 1,658,902 | 1,421,620 | | | |

The following table of imports by countries of origin and import districts includes all hydraulic cements except "white nonstaining portland cement," which was reported "imported for consumption" as follows: 1938, 12,227 barrels valued at $38,557, of which 5,439 barrels valued at $17,466 came from Belgium, 3,262 barrels valued at $6,394 from France, and 1,555 barrels valued at $5,892 from the United Kingdom; 1937, 12,808 barrels valued at $39,875, of which 4,214 barrels valued at $13,775 came from Belgium, 3,728 barrels valued at $13,691 from the United Kingdom, and 2,711 barrels valued at $6,000 from France.

[5] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

*Exports.*—Although the United States is the major cement-producing country of the world, its export trade is small. As indicated in the following table, exports have amounted to less than 1 percent of total domestic shipments during recent years. The value of exports is the actual cost at United States ports as indicated by the shippers on the export declarations.

*Hydraulic cement exported from the United States, 1934–38*

| Year | Barrels | Value | Percent of total shipments from mills |
|---|---|---|---|
| 1934 | 566,171 | $1,133,381 | 0.7 |
| 1935 | 416,099 | 1,012,942 | .6 |

## WORLD PRODUCTION

The following table of world production was compiled for the first time by the Bureau of Mines from consular reports, official statistics, and trade literature. The figures are in metric tons (1 metric ton equals 2,204.6 pounds). The table shows production from 1934 to 1938, inclusive, and the latest reported plant capacity. Although figures for certain countries are still lacking the table presents the most complete picture of the cement industry throughout the world that has yet appeared. Figures on capacity are the best estimates that can be made from available data and are subject to revision.

[1] Table includes all kinds of cement. Few data are available for Afghanistan, Burma, Eritrea, Ethiopia, Hong Kong, Luxemburg, Taiwan, and Venezuela, and they do not permit the establishment of production figures at this time, but estimates of production and capacity of these countries are included in the totals. The present plant capacity of China and Spain is in reality unknown owing to the destructive effects of military operations.

[2] Figures are approximate only and are subject to revision.

[3] Data not available, estimate included in total.

[4] Data not yet available.

[5] Approximate production.

*Canada.*—According to the Dominion Bureau of Statistics, sales of portland cement by Canadian producers declined 11 percent in quantity and 9 percent in value in 1938 compared with 1937. The Canadian Cement Co., Ltd., the largest producer, operated two plants in Quebec, two in Ontario, and one each in Manitoba and Alberta. Two smaller companies also produce cement in Canada, one in Ontario and the other in British Columbia. The following table presents the principal statistics of the Canadian industry.

*Salient statistics of the cement industry in Canada, 1937–38* [1]

| General conditions | 1119 | Crushed and broken stone | 1135 |
| Dimension stone | 1122 | Salient statistics | 1136 |
| Salient statistics | 1122 | Commercial and noncommercial operations | 1137 |
| Building stone | 1123 | Methods of transportation | 1138 |
| Granite | 1124 | Granite | 1138 |
| Basalt | 1126 | Basalt | 1140 |
| Marble | 1127 | Marble | 1141 |
| Limestone | 1128 | Limestone | 1141 |
| Sandstone | 1131 | Sandstone | 1145 |
| Miscellaneous stone | 1133 | Miscellaneous stone | 1147 |
| Trends in use of building and memorial stone | 1134 | Markets | 1149 |
| New developments | 1135 | New developments | 1150 |
| | | Foreign trade | 1151 |

The stone industries in 1938 failed to maintain the gains won in 1936 and 1937. Sales of both crushed and dimension stone dropped 6 percent in quantity and 5 percent in value compared with 1937. Dimension-stone sales (exclusive of slate) declined 6 percent in quantity and 10 percent in value, while crushed-stone sales (excluding that used for lime and cement manufacture) dropped 6 percent in quantity and 4 percent in value. Sales of stone depend to an unusual degree on the volume of building and highway construction. The building industries made substantial gains during the late months of 1938, with consequent stimulation of stone production, but the increase in output during that period was insufficient to overcome the decline in sales early in the year. Detailed figures of sales of stone by kinds and uses appear in following sections.

The present chapter follows the general plan of the chapter on Stone in Minerals Yearbook, 1938, data on dimension stone being separated from that on crushed stone, except in the introductory general tables.

The tables in this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by the producer is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show total sales of stone by kinds, uses, and States.

[1] Ganister, sandstone, mica schist, soapstone, and dolomite.

[2] Includes roofing granules, as follows: 1937, 168,150 tons valued at $761,928; 1938, 171,389 tons, $666.917. There were also produced slate granules used for roofing as follows: 1937, 277,010 tons valued at $1,578,014; 1938, 349,000 tons, $2,489,962. These figures are included in the chapter on Slate in this volume.

Digitized by Google

If sales in 1938 are compared with those in 1937 declines in all branches of the dimension-stone industries except rubble and curbing are evident. Sales of both crushed stone and riprap were considerably larger in 1938 than in 1937, but the output of furnace flux and refractory stone fell to unusually low levels.

## DIMENSION STONE

Total sales of dimension stone in 1938 declined 7 percent in quantity and 12 percent in value from 1937. These figures include slate, but details of the slate industry are given in a separate chapter of this volume. Sales of all varieties except miscellaneous stone were lower than in 1937; the latter, however, made a substantial gain in quantity but suffered a loss in value.

The following table of salient statistics includes final figures for both 1937 and 1938 and the percentage of change from 1937 for each type of stone by principal products.

*Dimension stone sold or used by producers in the United States, 1937–38, by kinds and uses*

| Kind and use | 1937 | 1938 | |
|---|---|---|---|
| | | Total | Percent of change |
| Granite: | | | |
| Building stone: | | | |
| Rough construction, short tons | 172,480 | 202,640 | +17.5 |
| Value | $386,267 | $343,984 | −10.9 |
| Average per ton | $2.24 | $1.70 | −24.1 |
| Cut stone, slabs, and mill blocks, cubic feet | 1,240,040 | 967,410 | −22.0 |
| Value | $2,681,888 | $2,460,649 | −8.2 |
| Average per cubic foot | $2.16 | $2.54 | +17.6 |
| Rubble, short tons | 111,140 | 108,220 | −2.6 |
| Value | $149,958 | $127,372 | −15.1 |
| Monumental stone, cubic feet | 2,657,630 | 2,092,540 | −21.3 |
| Value | $6,628,447 | $5,650,996 | −14.7 |
| Average per cubic foot | $2.49 | $2.70 | +8.4 |
| Paving blocks, number | 7,866,994 | 4,165,230 | −47.1 |
| Value | $780,611 | $452,542 | −42.0 |
| Curbing, cubic feet | 881,310 | 894,970 | +1.5 |

| Quantity, approximate short tons | 2,048,780 | 1,909,810 | −6.8 |
| Value | $28,359,845 | $24,943,513 | −12.0 |

[1] Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.
[2] Details of production, by uses, are given in the chapter on Slate in this volume.

## BUILDING STONE

The largest use of dimension stone is for building. The following table gives the quantity and value of each kind of stone used for construction in 1937 and 1938.

Digitized by Google

*Building stone sold or used by producers in the United States in 1938, by kinds*

| Kind | Rough | | | |
|---|---|---|---|---|
| | Construction | | Architectural | |
| | Cubic feet | Value | Cubic feet | Value |
| Granite | 2,449,520 | $343,984 | 311,570 | $238,820 |
| Basalt | 94,470 | 11,654 | | |
| Marble | | | 159,530 | 376,400 |
| Limestone | 2,006,460 | 316,772 | 2,455,580 | 895,791 |
| Sandstone | 829,450 | 190,419 | 64,100 | 42,389 |
| Miscellaneous | 262,020 | 42,707 | | |
| | 5,641,920 | 905,536 | 2,990,780 | 1,553,400 |

| Kind | Finished | | | | Total | |
|---|---|---|---|---|---|---|
| | Sawed [1] | | Cut [1] | | | |
| | Cubic feet | Value | Cubic feet | Value | Cubic feet | Value |
| Granite | 351,210 | $719,730 | 304,630 | $1,502,099 | 3,416,930 | $2,304,633 |
| Basalt | | | | | 94,470 | 11,654 |
| Marble | 149,650 | 423,977 | 378,110 | 2,464,500 | 687,290 | 3,264,877 |
| Limestone | 1,030,350 | 654,515 | 1,592,020 | 2,800,418 | 7,084,410 | 4,667,496 |
| Sandstone | 188,650 | 224,690 | 79,780 | 173,365 | 1,161,980 | 630,863 |
| Miscellaneous | | | 70,680 | 472,330 | 332,700 | 515,037 |
| | 1,719,860 | 2,022,912 | 2,425,220 | 7,412,712 | 12,777,780 | 11,894,560 |

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

## GRANITE

Sales of all granite products receded in 1938 both in quantity and value except rough construction stone and curbing, both of which gained in quantity but declined in value. The following table shows production by States and uses in 1938.

Digitized by Google

[2] 2,449,520 cubic feet (approximate).

Digitized by Google

The following tables show sales of monumental granite in the important Quincy (Mass.) and Barre (Vt.) centers.

*Monumental granite sold by the quarrymen at Quincy, Mass., 1934–38* [1]

| Year | Active plants | Cubic feet | Value | Year | Active plants | Cubic feet | Value |
|---|---|---|---|---|---|---|---|
| 1934 | 3 | 56,290 | $100,879 | 1937 | 3 | 36,020 | $80,248 |
| 1935 | 3 | 63,450 | 95,529 | 1938 | 3 | 33,360 | 73,832 |
| 1936 | 3 | 46,570 | 85,013 | | | | |

[1] Quincy granite is sold also for construction, curbing, rubble, riprap, and crushed stone.

*Monumental granite sold by the quarrymen in the Barre district, Vermont, 1934–38* [1]

| Year | Cubic feet | Value | Year | Cubic feet | Value |
|---|---|---|---|---|---|
| 1934 | 709,820 | $1,878,644 | 1937 | 847,740 | $2,390,377 |
| 1935 | 676,820 | 1,844,006 | 1938 | 605,660 | 1,849,607 |
| 1936 | 771,230 | 2,109,526 | | | |

[1] Barre granite is sold also for construction, paving blocks, and crushed stone.

*Estimated output of monumental granite in Barre district, Vermont, 1935–37* [1]

| | 1935 | 1936 | 1937 |
|---|---|---|---|
| Total quarry output, rough stock, cubic feet | 668,838 | 775,626 | 765,390 |
| Shipped out of Barre district in rough, do | 133,768 | 155,125 | 153,078 |
| Manufactured in Barre district, do | 535,070 | 620,501 | 612,312 |
| Light stock consumed in district, do | 418,024 | 484,766 | 478,369 |
| Dark stock consumed in district, do | 250,814 | 290,860 | 287,021 |

| Total pay roll for year | $2,232,000 | $2,852,000 | $2,852,000 |
| Estimated overhead | 1,116,000 | 1,426,000 | 1,426,000 |
| Estimated value of light stock | 1,358,577 | 1,575,490 | 1,554,699 |
| Estimated value of dark stock | 1,003,257 | 1,163,440 | 1,234,191 |
| Estimated polishing cost | 423,174 | 490,739 | 484,263 |
| Output from saws | 141,058 | 163,580 | 161,421 |
| Total value of granite | 6,274,066 | 7,671,249 | 7,712,574 |

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen; figures for 1938 not yet available.

## BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color basalt is not used extensively for building. As the table of salient statistics indicates, sales for building were only about half as great in 1938 as in 1937. Sales of rubble, however, made substantial gains. The following table shows production by States in 1938.

Basalt and related rocks are used for memorials, but such stones are classed commercially as black granites, therefore they are included with the figures for monumental granite.

Digitized by Google

*Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1938, by States and uses*

| State | Active plants | Building stone | | | | Total | |

## MARBLE

Sales of marble in 1938 dropped 7 percent in quantity and 3 percent in value. The decline would have been much greater were it not for the large gains by Tennessee which supplied exterior marble for the National Gallery of Art in Washington, D. C.

*Marble sold by producers in the United States, 1937–38, by uses*

| Use | | 1937 | | 1938 | |

[1] Includes 16,680 cubic feet of serpentine marble (verde antique) valued at $132,761, which was sold as building and ornamental stone.
[2] Included under "Undistributed."

## LIMESTONE

Limestone is used more extensively than any other type of building stone in the United States, and Indiana supplied 82 percent of the total architectural limestone (rough and finished) sold in 1938. Sales of cut stone, slabs, and mill blocks, which comprise the major products of the industry, decreased 7 percent in quantity and 8 percent in value in 1938 compared with 1937. The average price per cubic foot was 86 cents, the same as in 1937. Sales of stone for rough construction and for flagging declined greatly, but those of rubble made substantial gains.

## SANDSTONE

Sales of cut stone, slabs, and mill blocks of sandstone declined 27 percent in quantity and 32 percent in value in 1938. The output of stone for rough construction and rubble decreased greatly. Sales of paving blocks, which had dwindled almost to the vanishing point in 1937, increased more than tenfold in 1938. The output of curbing was much larger than in 1937, but sales of flagging were smaller. The average value of rough construction stone at the mill or quarry was higher than in 1937, and that of cut stone was lower.

## TRENDS IN THE USE OF BUILDING AND MEMORIAL STONE

Total building activity (residential plus nonresidential) in 1938 was just about the same as in 1937, while nonresidential building, where stone finds its chief market, receded moderately from the level of 1937. As indicated in figures 1 and 2, sales of building granite and

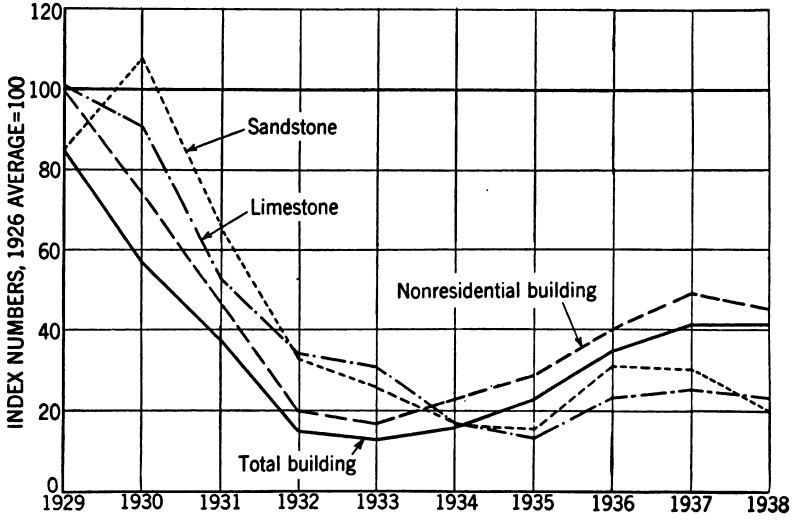

FIGURE 1.—Sales value of limestone and sandstone compared with total building and nonresidential building, 1929–38. To facilitate comparison, unlike units have been reduced to percentages of the 1926 value. Stone figures include rough and dressed stone; building contracts are from F. W. Dodge Corporation.

Digitized by Google

limestone declined to about the same extent as nonresidential building, and marble sales were almost as high as in 1937, but the output of building sandstone was only about two-thirds as great as in 1937. The encouraging upturn in building contracts awarded during the late months of 1938 did not have its full effect on stone sales, because actual construction on many of the contracts did not begin until 1939. The dignity, endurance, and fire resistance of natural stone should encourage its wider use in buildings of better class. A statistical history of building stone appeared recently,[1] which showed trends during recent years and discussed reasons for declining use.

Sales of memorial granite fell 21 percent, while the output of memorial marble remained virtually the same in 1938 as in 1937.

## NEW DEVELOPMENTS

In England the surfaces of limestone buildings have been cleaned effectively, even where the stone is encrusted with greasy soot, by applying a fine, misty spray of water to the surface for 1 or 2 hours before brushing.

In Europe unusually exhaustive study and research have been devoted to the weathering, discoloration, decay, frost-resistance, preservation, cleaning, and repair of building stones. These problems are of greater immediate importance in the older civilizations where stone buildings were erected centuries ago than in America where even our oldest stone structures are comparatively young from the standpoint of the life of high-grade building stone.

Blocks of natural sandstone known as "firestone" are being used to an increasing extent as refractories. Suitable material comes chiefly from the well-known sandstone area near Amherst in northern Ohio. The cementing material between the silica grains is amorphous silica, with small quantities of iron and alumina compounds. The structure is somewhat open, permitting expansion and contraction with little spalling at high temperature. Refractories of this type are well-adapted for lining soaking pits, bessemer converters, cupolas, and ladles.

Wire saws were used with fair success in 1938 in making major cuts in a marble quarry near Knoxville, Tenn. The average rate of cutting, including all delays, was 7.3 square feet per hour for a 24-hour day.

A publication [2] that may be of interest to stone producers was reprinted recently.

## CRUSHED AND BROKEN STONE

More than 123,000,000 tons of crushed and broken stone were sold in 1938 exclusive of that used for making cement and lime. Sales decreased 6 percent in quantity and 4 percent in value in 1938 compared with 1937. Encouraging gains in sales for the largest uses—highway construction and concrete aggregate—were more than offset by the notable decline in stone used by the iron and steel industries. The demand for stone in manufacturing plants (except sugar factories) also receded considerably from the level of 1937. Sales of agricultural limestone declined 13 percent.

*Commercial and noncommercial operations.*—The following table shows production of crushed stone for concrete and road metal and railroad ballast during recent years by Government agencies of various kinds contrasted with that by commercial enterprises. Production by Government agencies increased 32 percent in 1938 compared with 1937, while commercial production decreased 3 percent.

| Value | $48,427,045 | | $35,785,401 | | $84,212,446 | |

[1] Exclusive of railroad ballast, virtually all of which is shipped by rail.

## GRANITE

Sales of crushed granite increased 15 percent in quantity and 27 percent in value in 1938 compared with 1937. That used for concrete aggregate and road construction made only a small gain, but sales of both railroad ballast and riprap were far in advance of 1937 and the unit values of these products were much higher. The price of ballast per ton at the quarry increased from 65 cents to 88 cents and that of riprap from $1.07 to $1.44. A large part of the riprap production was noncommercial.

## BASALT

Basalt, gabbro, diorite, and other dark igneous rocks, known commercially as trap rock, are used widely for road building because of their toughness and excellent wearing qualities. Sales for this use and for concrete aggregate were about the same in 1938 as in 1937, but the output of riprap was nearly 2½ times as great as in 1937. The increase was general and consisted chiefly of the output of commercial companies. The larger output of New England was due to demands for stone to remedy the ravages of the hurricane. Prices of aggregates and road stone at the quarry were 4 cents a ton lower in 1938 than in 1937, and those of riprap were 5 cents lower.

*Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States in 1938, by States and uses*

## MARBLE

Marble may be used for virtually the same purposes as crushed limestone, and producers of building and monumental marble find outlets for waste stone in the form of crushed and pulverized products.

*Marble (crushed and broken stone) sold by producers in the United States in 1938, by States* [1]

| State | Active plants | Short tons | Value | State | Active plants | Short tons | Value |
|---|---|---|---|---|---|---|---|
| Alabama | 3 | 27,250 | $44,900 | Tennessee | 4 | 50,590 | $37,178 |

| Missouri | 1 | 11,780 | 17,344 | | | | |

[1] Includes stone used for artificial stone, crushed stone, flux, riprap, stucco, terrazzo, whiting substitute, and uses not specified.
[2] Arizona, California, New York, Virginia, and Washington.

## LIMESTONE

Limestone comprised 66 percent of all crushed and broken stone sold in 1938 (excluding that used for making cement and lime). It is employed more extensively than other rocks because it is widely distributed and therefore available to a multitude of markets and because it can be quarried and crushed at moderate cost. Furthermore, limestone is essential to many commodities and to a host of chemical and manufacturing processes. The following tables show production by States and uses during 1938 and sales for miscellaneous industrial uses.

| Stucco, terrazzo, and artificial stone | 36,180 | 152,788 | 23,360 | 146,828 |
| Sugar factories | 566,620 | 862,660 | 619,910 | 878,028 |
| Whiting substitute [1] | 194,080 | 923,494 | 145,170 | 671,842 |
| Other uses [2] | 173,000 | 328,768 | 80,350 | 89,447 |
| Use unspecified | 68,780 | 64,875 | 27,480 | 60,615 |
| | 8,636,070 | 8,424,338 | 6,780,400 | 7,073,004 |

[1] Includes stone for filler for graphite, calcimine, linoleum, paint, pigments, pottery, putty, regrinding, rubber, sealing wax, soap, tile, and uses not specified.

[2] Includes stone for acetic acid, acid neutralization, bird gravel, carbon dioxide, cement blocks, chemicals (unspecified), concrete blocks and pipes, dye works, explosives, fill, fireplace stone, foundry facings, lime burning, roofing gravel, sand, spalls, and waste rock.

Certain special uses of dolomite (calcium-magnesium carbonate) and its primary product of calcination, dolomitic lime, are covered in the following table:

*Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1937–38*

| | 1937 | 1938 |
|---|---|---|
| Dolomite for— | | |
| Basic magnesium carbonate: | | |
| Short tons | 96,730 | 62,540 |
| Value | $158,023 | $99,684 |
| Carbon dioxide | (1) | (1) |
| Dead-burned dolomite or refractory stone: | | |
| Short tons | 576,900 | 263,930 |
| Value | $580,720 | $274,624 |
| Dolomitic lime for— | | |
| Refractory (dead-burned dolomite): | | |
| Short tons | 617,706 | 366,626 |
| Value | $5,217,833 | $3,095,355 |
| Sulfite pulp: | | |
| Short tons | 43,000 | 39,000 |
| Value | $293,000 | $274,000 |
| Total (calculated as raw stone)—short tons | 1,995,000 | 1,168,000 |

Digitized by Google

Limestone is quarried not only for use in the raw state but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters of this volume. It is of interest, however, to show in one table the total tonnage of limestone used for all purposes.

*Limestone used for all purposes in the United States, 1936–38, in short tons*

| Use | 1936 | 1937 | 1938 |
|---|---|---|---|
| Limestone (as given in this report) (approximate) | 87,736,000 | 94,577,000 | 81,514,000 |
| Portland cement (including "cement rock") [1] | 28,650,000 | 29,547,000 | 26,183,000 |
| Natural cement ("cement rock") [1] | | | |
| Lime [2] | 7,500,000 | 8,250,000 | 6,694,000 |
| | 123,886,000 | 132,374,000 | 114,391,000 |

[1] Value reported as cement in the chapter on Cement.
[2] Value reported as lime in the chapter on Lime.

## SANDSTONE

The sandstone industry, which suffered a serious set-back in 1937, recovered remarkably in 1938. Sales increased 27 percent in quantity and 14 percent in value. Because of reduced activity in steel plants sales of refractory stone (ganister) declined greatly, but the output of riprap and stone for highway use and concrete aggregate made large gains.

## MISCELLANEOUS STONE

Stone other than the five principal varieties already discussed includes light-colored volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows production of such types of stone by uses in 1938.

*Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1938, by States and uses*

| State | Active plants | Riprap | | Crushed stone | | | | Other uses | | Total | |
|---|---|---|---|---|---|---|---|---|---|---|---|

## MARKETS

The consumption of concrete aggregates and roadstone ordinarily bears a fairly definite relationship to portland-cement shipments, area of new concrete pavements, and total building construction; but, as shown graphically in figure 3, aggregates made a much better showing in 1938 than the others. The commercial producer was not as fortunate as the chart would indicate, because the gain was in

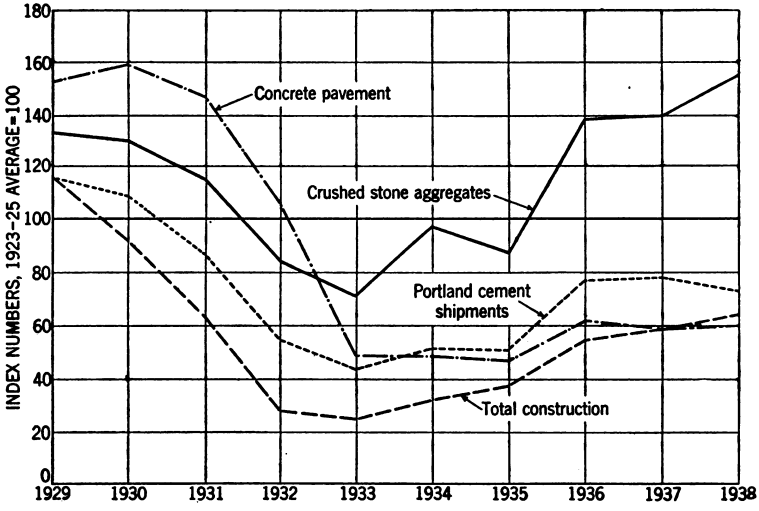

FIGURE 3.—Sales of crushed-stone aggregates (tons) compared with total construction, portland-cement shipments, and contracts for concrete pavements 1929–38. Data are plotted as index numbers with the 1923–25 average as 100. Figures on concrete pavements compiled by Portland Cement Association and on construction contracts by F. W. Dodge Corporation.

noncommercial production. Commercial production declined 3 percent in 1938, whereas noncommercial production increased 32 percent. The most logical explanation for the disproportionate increase in production of aggregates seems to be the fact that a large part of the stone produced at noncommercial quarries is employed on secondary roads and in other ways that have little connection with the other elements in figure 3.

Limestone is used extensively as a flux in blast furnaces producing pig iron and to a smaller extent in certain other smelting operations. Therefore a close relationship is to be expected between production of pig iron and sales of fluxing stone. Figure 4 shows the remarkable parallelism between these two industrial activities.

Digitized by Google

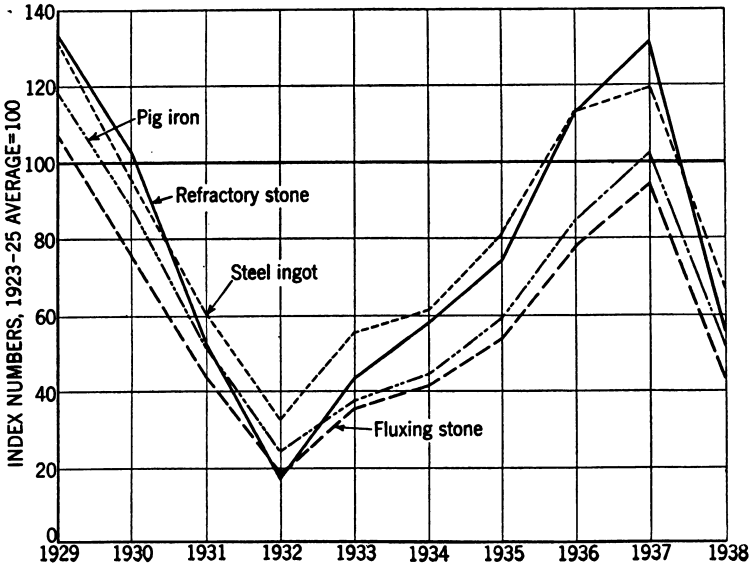

FIGURE 4.—Sales of fluxing stone and refractory stone (tons) compared with production of steel ingot and pig iron, 1929-38. All data are plotted as index numbers, with the 1923-25 average as 100. Statistics of steel-ingot and pig-iron production compiled by American Iron and Steel Institute.

Large quantities of dolomite and ganister are used as refractories in steel furnaces. Consumption of these products therefore fluctuates more or less in consonance with the changing pace of steel ingot production. Furnace relining is more active in some years than others, therefore the curves for steel ingot and refractory stone agree less closely than those for pig iron and fluxing stone.

## NEW DEVELOPMENTS

*Plants.*—The current trend toward the use of smaller stone in concrete mixtures has led to the installation of additional crushers and supplementary equipment at many crushed-stone plants. New grinding and screening equipment has been added at several plants to provide for a growing market for agricultural limestone.

A record of new crushing plants and remodeling of existing plants during 1938 may be found in the technical press.[3]

*Products.*—Stone sand is being used more widely as a substitute for silica sand as fine aggregate in concrete. Success in marketing this product can be expected principally where natural sand is not readily available. The grains must have proper shape and proper gradation; cubic or rounded particles are better than flat grains, and a lean concrete requires finer sand than a rich concrete. Stone sand is becoming an important byproduct at several limestone, dolomite, and granite quarries.

[3] Pit and Quarry, The Crushed-stone Industry in 1938: Vol. 31, Jan. 1939, pp. 91-97.

## FOREIGN TRADE [4]

*Imports.*—Foreign trade in stone is confined chiefly to dimension stone, but imports of quartzite from Canada are becoming increasingly important. Total imports in 1938 decreased 15 percent in value from 1937. The following table shows the quantities and values imported in 1938, by kinds. Imports of marble and rough granite declined greatly, but imports of dressed granite and miscellaneous stone products rose substantially, and those of travertine more than doubled. As indicated in the table of imports by countries of origin, imports of onyx marble from Mexico were smaller in 1938 than in 1937, while those from Argentina were larger in quantity but much smaller in value.

*Stone imported for consumption in the United States in 1938, by classes*

| Class | Quantity | Value | Class | Quantity | Value |
|---|---|---|---|---|---|
| Marble, breccia, and onyx: | | | Quartzite, short tons | 109,403 | $224,738 |
| In blocks, rough, etc., cubic feet | 54,582 | $197,284 | | | |
| Sawed, do | 170 | 873 | Travertine stone: Rough, cubic feet | 29,641 | 32,313 |
| Slabs or paving tiles, superficial feet | 177,125 | 55,585 | | | |
| All other manufactures | | 47,215 | Stone (other): | | |
| Mosaic cubes of marble or onyx: | | | Dressed | | 1,510 |
| Loose, pounds | 39,478 | 714 | Rough (monumental or building stone), cubic feet | 3,000 | 6,831 |
| | | | Rough (other), short tons | 9,684 | 21,882 |
| | | 301,671 | | | |
| Granite: | | | | | 30,223 |
| Dressed, cubic feet | 40,891 | 200,243 | | | |
| Rough, do | 30,523 | 49,330 | Grand total | | 838,518 |
| | 71,414 | 249,573 | | | |

*Exports.*—The export trade in stone is relatively small, and most of it is with Canada. The following table of exports appears in a new form because the export classification has been changed to combine marble with other building and monumental stone.

*Stone exported from the United States in 1938, by countries*

| Country | Marble and other building and monumental stone | | Other manufactures of stone (value) | Country | Marble and other building and monumental stone | | Other manufactures of stone (value) |

| Salient statistics | 1156 |
| Sales | 1156 |
| Dimension slate | 1156 |
| Granules and flour | 1157 |
| Trends in roofing slate | 1157 |
| Prices | 1158 |
| Trends in recent years | 1159 |
| Review by States and districts | 1159 |
| New developments | 1161 |
| Foreign trade | 1161 |

From the low point of the depression in 1933 the slate industry made steady gains until 1938 but suffered a severe setback in that year. The quantity of slate sold as dimension stone in 1938 dropped 14 percent and the value 21 percent compared with 1937. The substantial drop in prices per unit is noteworthy. If the reduced price is a measure of lower costs of production it may imply a more favorable competitive position for slate, but if it represents reduction of inventories and price cutting to levels approaching or lower than cost of production—a condition that has obtained in the slate industry repeatedly—one must infer that 1938 was in general an unprofitable year.

Roofing-slate sales declined relatively more in value than in quantity. The average value per square in 1938 was $6.98, whereas in 1937 it was $7.46. Sales in the Pennsylvania district dropped 11 percent in quantity and 17 percent in value compared with 1937. In the New York-Vermont district the quantity sold dropped 20 percent and the value 28 percent. In Virginia, however, sales increased 5 percent in quantity and 6 percent in value. The more favorable condition of the Virginia industry probably was due to the active residential building that characterized Washington, D. C., and its vicinity during 1938.

Sales of millstock declined 15 percent in quantity and 30 percent in value compared with 1937. Although building construction advanced from 59 percent of the 1923–25 average in 1937 to 64 percent in 1938, sales of structural and sanitary slate dropped 14 percent in quantity and 24 percent in value. Evidently slate is being replaced by other structural materials. The greatest decline experienced by any major branch of the slate industry was that of electrical slate, which dropped 63 percent in both quantity and value. Although high-grade slate is regarded as of superior quality for electrical panels and switchboards, it is apparent that various synthetic dielectric materials are being used to an increasing extent. Blackboards and bulletin boards maintained their position very well, for sales were off

Digitized by Google

only 1 percent in quantity and 3 percent in value. Billiard-table tops, which represent a relatively unimportant branch of the industry, made large gains in 1938. Sales of school slates decreased in quantity but gained in value. Sales of slate for vaults and covers and for flagging, cross walks, and stepping stones slumped greatly. Granules and flour, which have little connection with the slate industry, appear in the table because they are manufactured from slate, although much of the material so used is derived from deposits that could not be utilized for dimension-slate products. Granule sales made large gains in 1938, and the value per ton was $1.43 higher than in 1937.

The following table giving the principal statistical data for the slate industry during 1937 and 1938 is arranged to permit ready comparison for the 2 years:

*Salient statistics of the slate industry in the United States, 1937–38*

| 1937 | 365,800 | 137,400 | 2,728,109 | 21,480 | 1,225,645 | 8,670 | 73,554 | 167,550 | 4,027,308 |
| 1938 | 322,040 | 119,590 | 2,247,910 | 16,310 | 853,602 | 7,790 | 63,839 | 143,690 | 3,165,351 |

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

Figure 1 compares sales of slate, except granules and flour, with the value of contracts awarded for residential building and total building from 1929 to 1938. Slate sales followed closely the trends in building construction until 1938, but in that year slate experienced a radical decline.

*Granules and flour.*—Slate granules are used quite extensively for surfacing prepared roofing, and slate flour is employed as a filler in roofing mastic, linoleum, and other products. The following table shows sales of granules and flour by producers from 1934 to 1938:

*Crushed slate (granules and flour) sold by producers in the United States, 1934–38*

| Year | Granules | | Flour | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 123,290 | $902,078 | 42,870 | $164,022 | 166,160 | $1,066,100 |
| 1935 | 166,520 | 1,112,081 | 59,990 | 196,264 | 226,510 | 1,308,345 |
| 1936 | 202,730 | 1,372,095 | 86,920 | 274,685 | 289,650 | 1,646,780 |
| 1937 | 193,950 | 1,309,549 | 83,060 | 268,465 | 277,010 | 1,578,014 |
| 1938 | 258,930 | 2,220,306 | 90,070 | 269,656 | 349,000 | 2,489,962 |

*Trends in roofing slate.*—Residential building is the principal market for roofing slate. Slate is used for new construction and reroofing, but no figures are available as to the proportion used for each. New construction is, however, the principal market. No statistics are available on the roof area of new residential construction; but roof area bears a fairly definite relation to floor space, for which data are compiled. Floor space may therefore be regarded as a rough index of the area covered with roofing.

Figure 2 compares sales of roofing slate in squares with residential floor space of new construction from 1929 to 1938. The chart indicates that slate did not suffer as severe a recession as residential building from 1929 to 1934 and that in 1935 and 1936 slate sales gained more rapidly than construction contracts; however, in 1937 slate sales dropped slightly, and in 1938 they experienced a sharp decline, although floor space of new residential construction made moderate gains during these years.

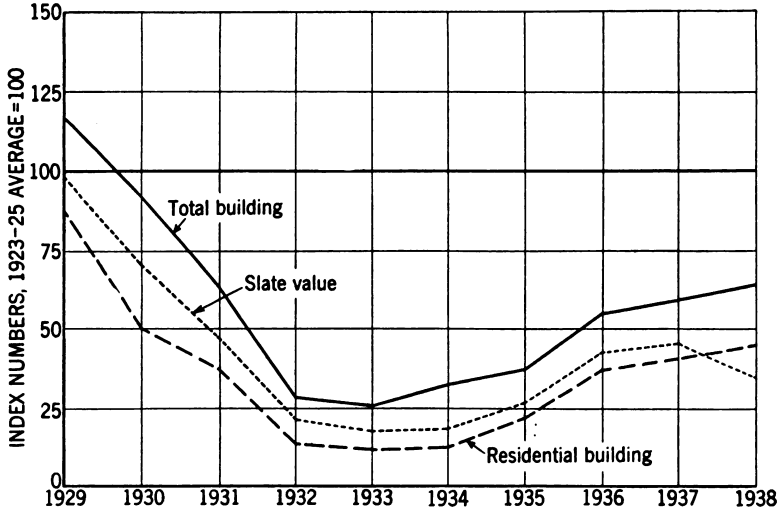

FIGURE 1.—Sales of slate compared with residential building and total building, 1929-38. Data on building from the F. W. Dodge Corporation.

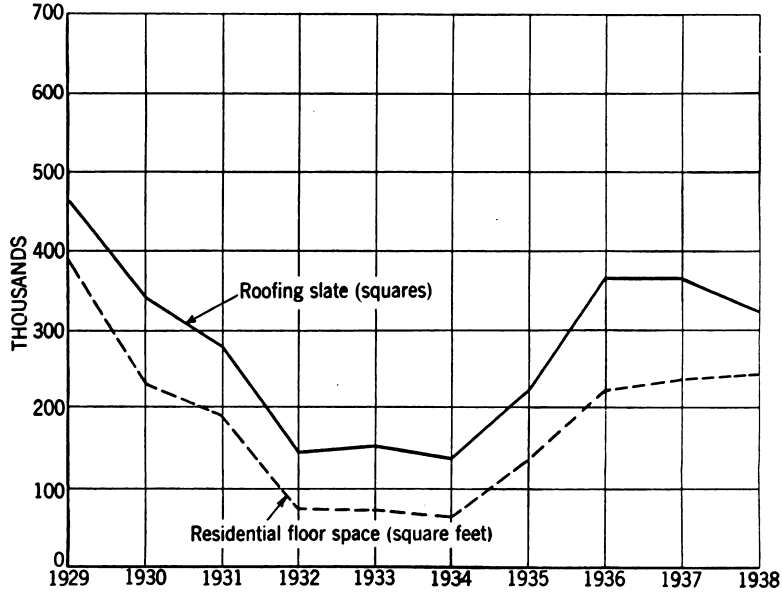

FIGURE 2.—Sales of roofing slate compared with residential floor space, 1929-38. Statistics on floor space from the F. W. Dodge Corporation.

## PRICES

Prices of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines by producers, declined 48 cents a square in 1938 compared with 1937. In Pennsylvania the price dropped 50 cents a square; in the New York-Vermont area, 75 cents; but in Virginia the price advanced 8 cents a square.

Digitized by Google

Average millstock prices fell from 29 cents a square foot in 1937 to 24 cents in 1938. Blackboards, bulletin boards, and electrical slate sold at 1 cent a square foot less than in 1937. Structural and sanitary slate fell 3 cents a square foot; vaults and covers advanced 2 cents, and school slates were a little higher than in 1937.

*Trends in recent years.*—Figure 3 shows the trend of slate prices over a 10-year period compared with prices of building materials in

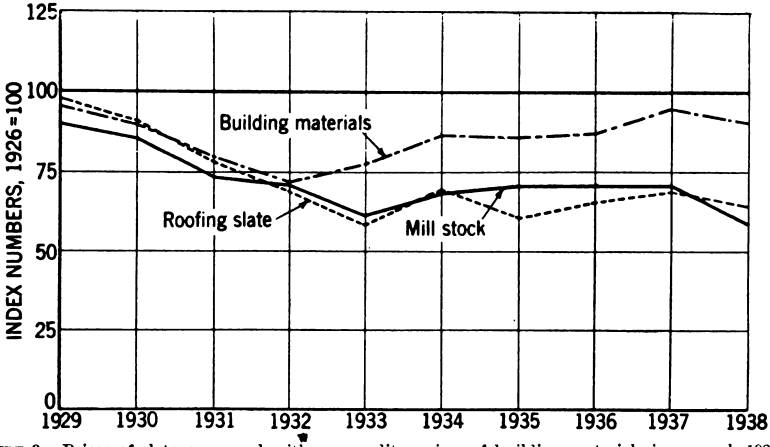

FIGURE 3.—Prices of slate compared with commodity prices of building materials in general, 1929-38. Commodity prices are from the Bureau of Labor Statistics.

general. The drop in price of roofing slate was comparable with that of building materials, but millstock prices fell abnormally.

## REVIEW BY STATES AND DISTRICTS

The following table shows sales of slate in 1938 by States and uses:

*Slate sold by producers in the United States in 1938, by States and uses*

| State | Operators | Roofing | | Millstock | | Other uses [1] (value) | Total value |
|---|---|---|---|---|---|---|---|
| | | Squares (100 square feet) | Value | Square feet | Value | | |
| Arkansas | 1 | | | | | (2) | (2) |
| California | 3 | | | | | $27,877 | $27,877 |
| Georgia | 1 | | | | | (2) | (2) |
| Maine | 2 | (2) | (2) | (2) | (2) | (2) | (2) |
| Maryland | 1 | | | | | (2) | (2) |
| New York | 17 | 2,780 | $26,340 | (2) | (2) | [3] 418,991 | 445,331 |
| Pennsylvania | 30 | 195,560 | 1,293,426 | 3,292,330 | $664,006 | 544,045 | 2,501,477 |
| Tennessee | 2 | (2) | (2) | (2) | (2) | (2) | (2) |
| Vermont | 51 | 83,490 | 577,279 | 135,750 | 68,279 | 1,084,097 | 1,729,655 |
| Virginia | 5 | 34,440 | 300,527 | | | 68,533 | 369,060 |
| Undistributed [4] | | 5,770 | 50,338 | 147,140 | 121,317 | 410,258 | 581,913 |
| | 113 | 322,040 | 2,247,910 | 3,575,220 | 853,602 | 2,553,801 | 5,655,313 |

[1] Flagging and similar products, granules, and flour.

[3] A small amount of millstock included under "Other uses."
[4] Includes output of States entered as "(2)" above.

159434—39——74

Digitized by Google

*Maine.*—The principal product of the Maine quarries is electrical slate, the production of which suffered the most serious decline in its history. The Rising & Nelson Slate Co. has discontinued its operations in Maine.

*New York-Vermont.*—The slate area on the New York-Vermont border furnishes attractive green, purple, mottled, and red roofing slates, but sales of these products dropped sharply in 1938. Sales of millstock were only about half as large as in 1937, but sales of granules and flour made decisive gains. The value of all slate products sold in Vermont in 1938 was 21 percent greater than in 1937, the increase in granule sales more than compensating for the drastic decline in other products.

*Peach Bottom district.*—The chief output of the Peach Bottom district on the Maryland-Pennsylvania border is granules, but excellent roofing slate is available. At present the Funkhouser Co. is the only producer of roofing slate in this area.

*Lehigh district.*—The Lehigh district, comprising Lehigh and Northampton Counties, Pa., is the most productive slate area in the United States and furnishes all types of slate products. As separate figures cannot be shown for York County, it is included with Northampton County in the table.

*Slate sold by producers in Pennsylvania in 1938, by counties and uses*

| County | Operators | Roofing slate | | Millstock [1] | | | |
|---|---|---|---|---|---|---|---|
| | | Squares (100 square feet) | Value | Electrical | | Structural and sanitary [2] | |
| | | | | Square feet | Value | Square feet | Value |
| Lehigh | 10 | 11,850 | $80,363 | 16,590 | $6,989 | 24,970 | $5,871 |
| Northampton and York [3] | 20 | 183,710 | 1,213,063 | 4,820 | 3,094 | 1,028,030 | 267,805 |
| | 30 | 195,560 | 1,293,426 | 21,410 | 10,083 | 1,053,000 | 273,676 |

| County | Millstock—Continued [1] | | | | Other uses (value) [4] | Total value |
|---|---|---|---|---|---|---|
| | Blackboards and bulletin boards | | School slates | | | |
| | Square feet | Value | Square feet | Value | | |
| Lehigh | 414,780 | $93,030 | [5] 520,200 | [5] $13,179 | ([6]) | [5] [6] $199,432 |
| Northampton and York [3] | 1,222,790 | 254,456 | ([5]) | ([5]) | [6] $563,627 | [5] [6] 2,302,045 |
| | 1,637,570 | 347,486 | 520,200 | 13,179 | 563,627 | 2,501,477 |

[1] Exclusive of billiard-table material, value of which is included under "Other uses."
[2] Includes slate for grave covers and vaults.
[3] York County produced roofing slate, granules, and flour only.
[4] Includes 60,150 square feet of billiard-table material valued at $19,582.
[5] Small amount of school slates produced in Northampton County included under Lehigh County.
[6] Small amount of flagging produced in Lehigh County included under Northampton and York Counties.

Sales of roofing slate in 1938 in the Lehigh district (and York County) decreased 11 percent in quantity and 17 percent in value from those in 1937. Electrical slate sales were only about one-third as great as in 1937, while structural and sanitary products and school slates exhibited a moderate decline. Sales of blackboards and bulletin boards were nearly as great as in 1937. Sales of billiard-

Digitized by Google

table material and granules alone gained in 1938. The value of total sales of slate products was 9 percent less in 1938 than in 1937.

*Virginia.*—The slate industry of Buckingham County is devoted chiefly to the production of roofing slate. Sales achieved a moderate gain with average prices a little higher than in 1938.

*Other districts.*—Arkansas, California, Georgia, and Tennessee reported a small output, chiefly of granules and flagging. The Maryland Slate Corporation, Silver Spring, Md., is reopening a quarry that was operated in a small way many years ago in Frederick County, Md. The principal product will be blue-black roofing slate similar to that obtained in the Peach Bottom district.

## NEW DEVELOPMENTS

Investigations by the Building Research Station of the Department of Scientific and Industrial Research, London, England, conducted a few years ago, indicated that when slate is calcined at a high temperature it is converted into a light, spongy mass that will float on water. Similar results were obtained by the Eastern Experiment Station of the Bureau of Mines by calcining Pennsylvania slate. If a satisfactory commercial product can be made, a market may be developed for waste slate in the form of light-weight aggregate.

A detailed discussion of the domestic and foreign slate industries has recently appeared.[1]

## FOREIGN TRADE[2]

*Imports.*—The value of slate imported for consumption in the United States in 1938 was 39 percent greater than in 1937, but imports are relatively unimportant. The following table shows the value of imports in 1937 and 1938 by countries:

*Slate imported for consumption in the United States, 1937–38, by countries*

| Country | 1937 | 1938 | Country | 1937 | 1938 |
|---|---|---|---|---|---|
| Canada | $826 | $543 | Italy | $349 | $994 |
| China | | 3 | Japan | 222 | 68 |
| Czechoslovakia | 990 | 1,037 | Norway | 381 | |
| France | | 895 | United Kingdom | 2,019 | 3,089 |
| Germany | 17 | | | | |
| Hong Kong | 20 | 59 | | 4,824 | 6,688 |

*Exports.*—In 1936 and following years exports of roofing slate were included with exports of stone in the tabulations of the Bureau of Foreign and Domestic Commerce; therefore separate figures from that source cannot be given. The following table shows exports of slate products from 1936 to 1938, as reported to the Bureau of Mines by shippers. Roofing, electrical, billiard tables, and structural slate exports show large declines; school slates, a moderate gain; and blackboards, a large gain. Slate granules and flour evidence a small gain in quantity and a larger gain in value.

[1] Figures collected by Bureau of Mines from shippers of products named.
[2] Figures not available.
[3] Cases weigh 130 to 165 pounds each; average is 135 pounds. They contain 8 to 18 dozen slates, depending on size. Sizes run from 5 by 7 to 9 by 13 inches (inside frame).
[4] Includes slate for floors and walkways.
[5] Excludes roofing.

# SAND AND GRAVEL

By H. Herbert Hughes and G. Egge

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1163 | Production—Continued. | |
| Salient statistics | 1164 | Size of plants | 1175 |
| Production | 1166 | Prices | 1175 |
| Noncommercial operations | 1172 | New developments | 1176 |
| Method of transport | 1174 | Foreign trade | 1176 |
| Preparation | 1174 | Blast-furnace slag | 1177 |

Outstanding in the sand and gravel industry in 1938 was the further shift to noncommercial operations for supplies of aggregates. The output of plants operated by States, counties, municipalities, and other Government agencies, as reported to the Bureau of Mines, was 17 percent higher than in 1937 and comprised 42 percent of the total tonnage. Commercial production dropped 16 percent. The

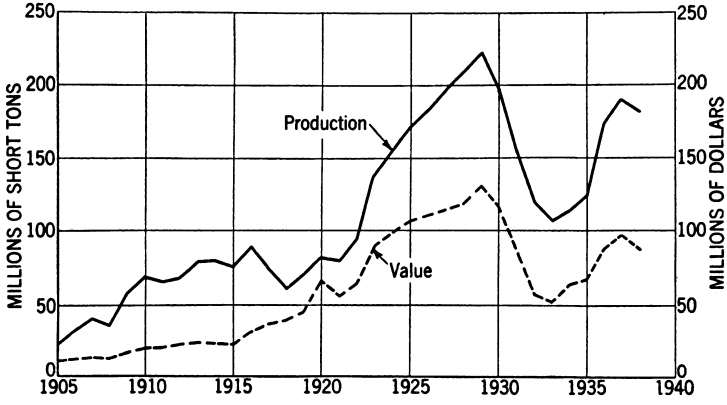

Figure 1.—Principal trends in the sand and gravel industry, 1905-38.

total quantity of sand and gravel sold or used for all purposes decreased 4 percent from 1937, and this decline correlates closely with statistics of construction and other indicators of outlets for sand and gravel. The drop in 1938 interrupted the continuous rise from the low in 1933. (See fig. 1.)

The total value of construction contracts awarded in 1938 was 10 percent higher than in 1937, but this rise was due entirely to sharp gains late in the year which, for the most part, did not result

Digitized by Google

in demand for materials until early in 1939. A similar situation existed in contracts awarded for engineering construction and concrete paving, which advanced 15 and 11 percent, respectively. Construction financed by public funds increased 48 percent and contracts for public works 45 percent in 1938 compared with 1937. Despite a drop of 15 percent in privately financed construction, residential contract awards were 9 percent above 1937. Residential construction was particularly active in the last quarter of 1938.

In general, prices of sand and gravel in 1938 were slightly below those in 1937, although producers reported an increase in the average value per ton for some industrial sands. In 1938, as in earlier years, the average value of the noncommercial output was low—a reflection of the high percentage of unprepared material included in this category.

Salient statistics of the sand and gravel industry in 1937 and 1938 are summarized in the following table.

*Sand and gravel sold or used by producers in the United States, 1937–38, by commercial and noncommercial operations and by uses*

| | 1937 | | | 1938 | | | | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | | Short tons | Value | | Percent of change in— | |

| Grand total | 189,660,423 | 97,472,997 | .51 | 181,320,233 | 85,922,847 | .47 | −4.4 | −7.8 |

[1] Includes 205,753 tons of blast sand valued at $509,178.

[2] Includes some sand used for fills and similar purposes. The quantity of sand reported as used exclusively for railroad ballast in 1937 was 1,330,204 tons valued at $315,988 and in 1938, 672,829 tons, $195,469. The figures include sand produced by railroads for their own use as follows—1937: Ballast, 201,488 tons, $21,363, and fills and similar purposes, 88,112 tons, $18,597; 1938: Ballast, 128,079 tons, $25,806, and fills and similar purposes, 113,606 tons, $17,466.

[3] Includes some gravel used for fills and similar purposes. The quantity of gravel reported as used exclusively for railroad ballast in 1937 was 11,527,192 tons valued at $3,650,278 and in 1938, 7,271,502 tons, $2,179,462. The figures include gravel produced by railroads for their own use as follows—1937: Ballast, 5,343,956 tons, $843,851, and fills and similar purposes, 791,383 tons, $106,790; 1938: Ballast, 3,590,684 tons, $645,133, and fills and similar purposes, 922,742 tons, $75,893.

[4] By States, counties, municipalities, and other Government agencies directly or under lease.

Sales of sand and gravel by commercial producers for all major uses were lower in 1938 than in 1937. Sales of paving sand and gravel dropped 4 and 3 percent, respectively, whereas output of noncommercial paving sand and gravel increased appreciably. This would seem to indicate increased activity in low-cost road construction, but a drop of 9 percent in road-oil sales and increases of 11 and 9 percent, respectively, in concrete paving and domestic demand for asphalt do not support this inference.

As was indicated by data on construction, total sales of building sand and gravel in 1938 were 9 and 5 percent, respectively, lower than in 1937. Sharp increases of 40 and nearly 150 percent in noncommercial building sand and gravel failed to offset decreases of 12 and 24 percent, respectively, in commercial output. The rise in noncommercial production was related to the WPA program.

Sales of some industrial sands were less than half those in 1937. The output of glass sand was 25 percent lower in 1938, owing to decreases of 18 and 56 percent, respectively, in production of glass containers and polished plate glass. Curtailment of activity in the iron

Digitized by Google

and steel and foundry industries resulted in declines of more than 50 percent in output of molding and fire or furnace sands. Grinding and polishing sand also dropped more than 50 percent. Sharp decreases in engine sand and railroad-ballast sand and gravel were due to the continued depressed condition of the railroads. The output of filter sand dropped only 6 percent. The only increase in quantity in 1938 was in material unclassified as to use.

## PRODUCTION

Except for small supplies to meet seasonal peaks, stocks are of little consequence in the sand and gravel industry, and the quantity of materials sold or used by producers is virtually equivalent to production. Throughout this report sales and production are used interchangeably.

The relative importance of gravel continued to increase in 1938. It comprised 69 percent of the total tonnage compared with 67 percent in 1937 and only 53 percent in 1928. This increase shows that the use of gravel is expanding, although a large part of the rise represents noncommercial production used in low-type roads.

Complete production data for 1938 are included in this report. Statistics of sand and gravel sold or used by commercial and noncommercial producers from 1934 to 1938 are summarized in the following table.

*Sand and gravel sold or used by commercial and noncommercial producers in the United States, 1934–38*

| Year | Sand | | Gravel (including railroad ballast) | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 38,400,090 | $24,881,071 | 78,211,599 | $36,366,102 | 116,611,689 | $61,247,173 |
| 1935 | 40,433,559 | 25,867,222 | 83,490,364 | 36,110,157 | 123,923,923 | 61,977,379 |
| 1936 | 60,303,394 | 35,926,994 | 118,026,420 | 54,380,758 | 178,329,814 | 90,307,752 |
| 1937 | 63,385,071 | 40,412,497 | 126,275,352 | 57,060,500 | 189,660,423 | 97,472,997 |
| 1938 | 57,113,828 | 33,935,725 | 124,206,405 | 51,987,122 | 181,320,233 | 85,922,847 |

New York, Illinois, and California led all States in output of sand and gravel in 1938, although Pennsylvania ranked third on the basis of value because of its large production of glass and other high-priced industrial sands. Details of production in 1938 by States and uses are given in the following tables. This year, for the first time, the table by States is designed to show the break-down by commercial and noncommercial producers.

[1] Included under "Undistributed."
[2] Includes items entered as "1."
[3] Includes 205,753 tons of blast sand valued at $509,178.
[4] Includes some sand used for fills and similar purposes. The quantity of sand reported as used exclusively for railroad ballast was 672,829 tons valued at $195,469. The figures include sand produced by railroads for their own use as follows: Ballast, 128,079 tons, $25,806, and fills and similar purposes, 113,606 tons, $17,466.
[5] Includes some gravel used for fills and similar purposes. The quantity of gravel reported as used exclusively for railroad ballast was 7,271,502 tons valued at $2,179,462. The figures include gravel produced by railroads for their own use as follows: Ballast, 3,590,684 tons, $645,133, and fills and similar purposes. 922,742 tons, $75,893.
[6] May include some gravel used by railroads for fills and miscellaneous purposes.

*Noncommercial operations.*—Recapitulations to show statistics of sand and gravel reported by States, counties, municipalities, and other Government agencies have now been carried back through 1923,

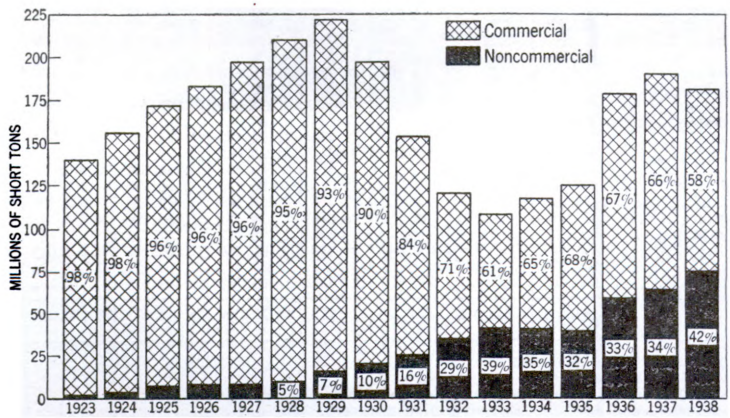

FIGURE 2.—Sand and gravel sold or used in the United States by commercial and noncommercial producers, 1923–38.

although the separate canvass of this material from noncommercial operations was not begun until 1932. Noncommercial production amounted to less than 2 percent of the total output in 1923, but during the depression it rose to more than a third of the total and in 1938 to 42 percent. (See fig. 2.)

Digitized by Google

The complete record of noncommercial production since 1923 is summarized in the following table:

*Sand and gravel sold or used by noncommercial producers in the United States, 1923–38, by uses*

| Year | Sand | | | | Gravel | | | | Total noncommercial sand and gravel | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Building | | Paving | | Building | | Paving | | | |
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |
| 1923 | [1] 75,392 | [1] $61,990 | 205,282 | $113,174 | 5,994 | $4,534 | 1,828,808 | $1,165,617 | 2,115,476 | $1,345,315 |

| 1937 | 1,540,280 | 595,953 | 4,704,764 | 1,157,162 | 2,961,360 | 1,396,202 | 55,111,541 | 15,209,362 | 64,317,945 | 18,358,679 |
| 1938 | 2,157,501 | 890,224 | 6,623,073 | 1,373,556 | 7,299,822 | 2,454,783 | 59,480,051 | 16,188,406 | 75,560,447 | 20,906,969 |

[1] Includes a small quantity of filter sand.

In 1938, as in earlier years, most of the output of noncommercial operations (79 percent) was paving gravel, largely unprepared material for use in low-cost secondary roads. Building-sand and gravel output rose sharply to 13 percent of the total compared with only 7 percent in 1937.

Sand and gravel classed as noncommercial includes that reported by States, counties, municipalities, or other Government agencies, produced either by their own construction or maintenance crews or by contractors expressly for their consumption. Purchases from commercial producers are not included. The quantity produced by contractors was 41 percent of the total in 1938 and 40 percent in 1937. In 1938, as in previous years, more than half the production of noncommercial material was reported by States, about one-third by counties, and the rest by municipalities and other agencies. Details are given in the following table.

*Sand and gravel sold or used by noncommercial producers in the United States, 1935–38, by types of producers*

| Type of producer | 1935 | | 1936 | | 1937 | | 1938 | |
|---|---|---|---|---|---|---|---|---|

*Method of transport.*—Shipments of sand and gravel originating on class I railroads in 1938 were 28,384,563 short tons, a drop of 24 percent from the 37,546,068 tons in 1937. This quantity was only 31 percent of the total commercial production reported in 1938, exclusive of glass and molding sand and nonrevenue railroad ballast. The figure indicates a continuing increase in the quantity of sand and gravel moved by other means than rail, as rail shipments were equivalent to 36 percent of commercial production in 1937 and 40 percent in 1936.

Direct reports of methods of transporting sand and gravel were received from producers responsible for 86 percent of the total commercial output. These figures not only show a decided drop in the relative magnitude of rail shipments but also a corresponding increase in shipments by truck and by waterway. Details of shipments, by methods of transport, follow.

*Sand and gravel sold or used by commercial producers in the United States, 1937–38, by methods of transport* [1]

| Method of transport | 1937 | | 1938 | |

| Waterway | 14,534,833 | 13.3 | 14,278,779 | 15.7 |
| Total reported | 108,976,680 | 100.0 | 91,096,810 | 100.0 |
| Percent of total commercial production | | 86.9 | | 86.1 |

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, sand and gravel moved as follows—1937: Truck 61 percent, rail 31 percent, and waterway 8 percent; 1938: Truck 69 percent, rail 23 percent, and waterway 8 percent.

*Preparation.*—The higher average value per ton of sand and gravel reported by commercial producers compared with noncommercial output is a direct result of the cost of washing, screening, or other preparation. In 1938, 88 percent of the commercial production was prepared material, but only 18 percent of the noncommercial output was treated.

*Size of plants.*—Most sand and gravel plants are small. In 1938, 57 percent of all commercial plants reported sales of less than 25,000 tons each and 88 percent of less than 100,000 tons. These two groups produced 10 and 44 percent, respectively, of the total output. There has been a semblance of a trend toward smaller plants in the past few years, as 86 percent of the plants in 1931 reported less than 100,000 tons each and represented only 32 percent of the total tonnage. The following table gives details of production by size groups in 1937 and 1938.

*Comparison of number and output of commercial sand and gravel plants in 1937 and 1938, by size groups* [1]

[1] Plants operated by or for States, counties, and municipalities are not included; also not included are 194 railroad plants with an output of 6,559,000 short tons of sand and gravel in 1937 and 186 plants with an output of 4,941,000 tons in 1938.

[2] May include a few companies operating more than 1 plant but not submitting separate returns for individual plants.

[3] Less than 0.1 percent.

[4] Combined to avoid revealing production of individual plants.

## PRICES

Despite the drop in demand for sand and gravel for all important uses in 1938, prices changed little from those in 1937. The average value per ton, f. o. b. plant, of all sand and gravel reported by commercial producers fell only 3 percent—from $0.63 in 1937 to $0.61 in 1938. The sharpest decrease was in the value of filter sand and miscellaneous gravel, although engine and building sand as well as building and railroad ballast gravel also declined. The value of sand sold for various other purposes increased moderately, while that of paving gravel was unchanged.

Wholesale price indexes for sand and gravel, compiled by the Bureau of Labor Statistics from returns from about 30 plants throughout the United States, confirm the moderate decreases indicated by reports of producers to the Bureau of Mines. The price index of building sand (1926=100) declined only slightly, from 102.5 in 1937 to 102.1 in 1938, and that of gravel dropped from 94.2 to 93.2. These indexes are particularly significant when compared with other prices. The index

Digitized by Google

for all building materials dropped from 95.2 in 1937 to 90.3 in 1938, and the general index for all commodities slumped from 86.3 to 78.6.

This relative stability of sand and gravel prices, despite declining prices for virtually all other commodities, was an outstanding feature of the industry in 1938.

## NEW DEVELOPMENTS

Notwithstanding the drop in output in 1938, construction of new sand and gravel plants and remodeling of old plants through the installation of new equipment kept pace with 1937.[1] No outstandingly large plants were built in 1938; most of the new operations are designed to serve relatively small market areas, and some have facilities only for truck shipments. Many plants have been rebuilt, not so much to increase capacity or effect economies as to fill the demand for materials to meet new and changing specifications. As a matter of fact, the necessity for producing additional sizes of aggregates in many instances actually may have resulted in an increase in operating costs.[2] Several plants are now splitting their sand output into two or more size fractions and recombining them to meet varying specifications.

The National Sand and Gravel Research Foundation was established at the University of Maryland early in 1938. Modern equipment includes machines for strength tests of concrete and other materials, devices for abrasion tests of aggregates, a constant-temperature room, and other smaller equipment commonly found in construction-materials testing laboratories.

A preliminary study involving determination of the modulus of elasticity of concrete by sonic vibrations is being carried on in cooperation with the Eastern Experiment Station of the Bureau of Mines. This investigation may lead to a wider use of concrete in mine structures, will provide additional valuable information on the modulus of elasticity of concrete, and may point the way to further studies of the soundness of concrete and aggregates. Under way also are an investigation of the mortar-making characteristics of sand, continuation of the study of the adhesion of bitumens to aggregates, and a general study of the physical characteristics of miscellaneous aggregates.

## FOREIGN TRADE[3]

Imports of sand and gravel increased in 1938, but, as in 1937, the entire gain was in the movement of construction materials from Canada. Imports of glass sand, virtually all from Belgium and consigned to the Pacific coast glass industry, decreased 34 percent.

Exports of sand and gravel dropped sharply, but the quantity of material involved is so small that they are of little consequence.

## BLAST-FURNACE SLAG

The principal material competing with gravel is crushed stone, statistics for which appear in the Stone chapter of this and previous volumes of the Minerals Yearbook and Mineral Resources series. Blast-furnace slag is also important in the same markets in some areas.

In 1938, for the first time, the National Slag Association canvassed 34 companies operating 70 plants engaged in preparing blast-furnace slag for market. The total output of air-cooled and granulated slag was 7,978,066 tons valued at $6,246,615. This quantity was equivalent to 14 percent of the total commercial-gravel production. The following tables give detailed statistics of blast-furnace slag sold or used by producers in the United States in 1938, by regions and by uses.

# GYPSUM

By Forrest T. Moyer

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1179 | Recent developments | 1185 |
| Salient statistics | 1180 | Foreign trade | 1186 |
| Domestic production | 1180 | World production | 1187 |
| Distribution of sales | 1182 | | |

Activity in the gypsum industry was generally slower in 1938 than in 1937, as is illustrated by the 7-percent decrease in value of total sales of gypsum products. Although 1937 was the best year for the industry since 1932, depressing influences prevailing at its close carried over into the early part of 1938, and the progressive recovery during the second and third quarters of 1938 was little more than seasonal. Not until the fourth quarter was improvement definitely under way, and this was the only period in which sales of gypsum products gained over those in the corresponding quarter of 1937.

Of outstanding interest was the continued climb in sales of gypsum lath to a new high record. The present uptrend in consumption of this product began in 1935 and continued through 1938. It is significant that, as measured by the usual sales units (square feet for gypsum boards and short tons for plasters), lath is the only gypsum building product for which Bureau of Mines figures indicate an increase over 1937.

More active development of markets in the Southeastern States is indicated by the erection of processing mills by two gypsum companies. These mills, one in Georgia and one in Florida, began production of a complete line of gypsum products in the early part of 1939. They use crude gypsum imported from Canada. Formerly this area contained only two gypsum plants, one in Florida and the other in southwest Virginia. The large increase in productive capacity should promote larger consumption of gypsum products in the South.

The general welfare of the gypsum industry depends on building construction, which annually consumes more than 90 percent of the total value of all gypsum products sold or used in the country. As shown by data of the F. W. Dodge Corporation, the value of residential and nonresidential building contracts awarded in 1938 was virtually unchanged from that in 1937. Although building activity rose more or less steadily from the relatively low level that prevailed at the close of 1937, the gypsum industry in 1938 did not enjoy the full benefit of the indicated increase because of the lag of possibly 3 or 4 months between the time of contract award and the purchase of gypsum products. Consequently, much of the increased business

Digitized by Google

forecast by the growing volume of building contracts during the latter part of 1938 did not reach the gypsum producer until the first half of 1939.

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment; beginning in 1937 plants utilizing byproduct gypsum are included.
[2] To avoid revealing confidential data, byproduct gypsum is excluded.
[3] Data not collected.
[4] Includes byproduct gypsum.
[5] Gypsum products from domestic and imported crude.
[6] Revised figures.

The accompanying table of salient statistics shows moderate declines for all phases of the gypsum industry in 1938 compared with 1937, except the limited export trade, which increased slightly in value. The drop from 1937 of 482,016 short tons (12 percent) in the apparent supply of crude gypsum was shared equally by domestic mines and importations. This proportional decrease in tonnage from both sources indicates the balanced relationship in 1938 between the utilized capacity of plants processing imported material and those using domestic crude. The decreases of 7 percent in the quantity of calcined gypsum produced (kettle and kiln output) and the value of all products sold or used, compared with 1937, give a more accurate picture of the condition of the industry in 1938 than that indicated by the greater decline in the crude supply. Sales of uncalcined products fell 12 percent below 1937 in both tonnage and value; but sales of calcined products, which constitute the major part of the gypsum business, declined only 3 percent in tonnage and 6 percent in value. This greater decrease in value was due to the lowering of the prices of several types of calcined gypsum products. The value of all gypsum and gypsum products imported during 1938 again exceeded the value of exports by approximately 3 to 1, chiefly because of the large tonnage of crude gypsum imported for processing into products.

## DOMESTIC PRODUCTION

Domestic supplies of crude gypsum were obtained from 56 active operations including 28 underground mines, 22 quarries, and 6 combinations of underground mines and quarries. Operations were

Digitized by Google

active in 16 States throughout the country; New York had the greatest number. As shown in the following table, production declined from 1937 in all of the States except Nevada and Montana where slight gains were recorded. Ranking States in order of tonnage were New York, Michigan, Iowa, and Texas. Underground mining, which is common practice in the East and Middle West, produced more than half the domestic crude supply in 1938.

| | 59 | 2,712,510 | 58 | 3,058,166 | 4,782,503 | 56 | 2,684,205 | 4,271,674 |

[1] Value of crude gypsum mined not available.
[2] 1936–37: 1 active mine each in Arizona, Idaho, South Dakota, and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia. 1938: 1 active mine each in Idaho, South Dakota, and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia.

The value of the run-of-mine gypsum reported in the table is estimated by the producers, and as there is no open market for this material the figure is presumably a so-called "transfer value," which may represent only the actual cost of mining (including depreciation, depletion, etc.). In some instances the value returned by a producer may be only an estimate of a probable open-market price for the material. In 1938 the average value returned by producers was $1.59 per ton. The data on natural crude gypsum do not include the tonnage and value of crude byproduct gypsum utilized.

*Number of active calcining plants, kettles, and rotary kilns in the United States, 1936–38, by States*

| State | 1936 | | | 1937 [1] | | | 1938 [1] | | |

[1] Includes plants and equipment for calcining byproduct gypsum.
[2] Includes 3 vertical kilns.
[3] Includes 2 beehive kilns.
[4] 1936: 1 calcining plant each in Arizona, Connecticut, Indiana, Massachusetts, Nevada, New Hampshire, New Jersey, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, Ohio, Oklahoma, and Virginia. 1937: 1 calcining plant each in Arizona, Connecticut, Florida, Illinois, Indiana, Massachusetts, Nevada, New Hampshire, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, New Jersey, Ohio, Oklahoma, and Virginia. 1938: 1 calcining plant each in Arizona, Connecticut, Florida, Illinois, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, New Jersey, Ohio, and Virginia.
[5] Includes 4 beehive kilns.

Digitized by Google

The foregoing table shows that calcining plants were operated in 25 States during 1938. There were 54 active plants, and of these 41 operated on domestic crude, 11 on imported, and 2 on crude byproduct gypsum. Two plants, one using domestic and the other using by-product material, were abandoned in the latter part of the year.

## DISTRIBUTION OF SALES

In 1938 sales of the three general groups of gypsum products—uncalcined, calcined building, and calcined industrial—declined in both quantity and value from 1937 figures. Gypsum sold for use as portland-cement retarder, which constitutes by far the greater part of all raw or uncalcined shipments, fell 12 percent in tonnage and 15 percent in value below 1937. The average value per ton (f. o. b. plant) for this material declined 6 cents from the 1937 figure to $1.84 per ton in 1938. Sales of agricultural gypsum, used chiefly by the peanut growers of Virginia and to correct alkali soils, declined more in quantity (9 percent) than in value (4 percent). A slight increase in the use of finely ground uncalcined products such as fillers is indicated by the rise in the average value per ton of sales for "Other uses" from $7.93 in 1937 to $8.84 in 1938.

Sales of calcined building products declined only 2 percent in quantity from 1937, because increases in the gross tonnages of gypsum-lath and wallboard sales nearly balanced the weight losses of plasters and tile. However, the total value of this group of products fell 6 percent below 1937, on account of decreases in the average value per unit of gauging, molding, and package plasters, as well as gypsum board. Plasters (fibered and unfibered) sold for use in base-coat work, which comprise the largest tonnage of calcined building products, declined 10 percent in quantity and 11 percent in value from 1937. In contrast, sales of gauging and molding plasters, which are used in the finishing coat, fell only 2 percent in tonnage but 6 percent in value from 1937. The greater proportional decline in tonnage of base-coat plasters may be explained by the increased use of gypsum lath on which there appears to be an unfortunate tendency to use thin scratch and brown coats or to eliminate entirely the brown coat. Sales of the class "Other plasters," which is composed largely of the so-called package plasters sold in small units, showed a large decline of $14.03 in the average value per ton from 1937. As shown in the following table, sales of the remaining classes of building plasters and Keene's cement declined various amounts from the 1937 figures. The rather high declines of 16 percent in both square footage and value of sales of all tile (partition, roofing, soffit, etc.) probably resulted from the relatively small total of commercial and industrial building during 1938.

[1] Includes uncalcined gypsum sold for use as filler and rock dust, in paint manufacturing, and for minor purposes.
[2] Includes joint filler, patching and painter's plaster, and unclassified building plasters.
[3] Revised figures.
[4] 1937: 738,928,559 square feet; 1938: 809,470,931 square feet.
[5] 1937: 385,306,845 square feet; 1938: 371,766,937 square feet.
[6] 1937: 23,819,738 square feet; 1938: 19,941,993 square feet.
[7] Included under "For other manufacturing uses."
[8] Includes in 1937, orthopedic, dental, statuary, industrial molding and casting plasters, dead-burned filler, and miscellaneous sales; in 1938, statuary, industrial casting and molding plasters, dead-burned filler, and miscellaneous sales.

In 1938 total shipments of calcined products used in manufacturing processes declined 25 percent in quantity and 15 percent in value from 1937. The greatest decrease was in calcined gypsum sold to the plate-glass and terra-cotta industries and was occasioned by the low levels at which these industries operated until near the end of 1938.

The square footage of gypsum-lath sales rose to a new record during 1938, increasing 10 percent over 1937. This increase was accompanied by a decrease in unit value of 29 cents from 1937 to a sales value (f. o. b. plant) of $12.71 per thousand square feet in 1938. Both the square footage and total value of wallboard shipments dropped below 1937 figures, and the average value per thousand square feet decreased slightly. The gross tonnages of sales of both lath and wallboard, which are estimated by the producers, showed substantial gains over 1937. These gains indicate either an increase in average weight per thousand square feet or increased sales of the thicker sizes of both types of board. The average number of square feet per ton in 1938

Digitized by Google

was 1,361 for lath and 1,377 for wallboard as contrasted with corresponding figures for 1937 of 1,572 and 1,598.

Figure 1 shows the phenomenal expansion in sales of gypsum lath since 1928, the first year for which data are available. In the figure the square footage of lath and wallboard sold by selected companies and the total tonnage of all calcined gypsum building products are compared with the total floor area in square feet of all residential and nonresidential building contracts as reported by the F. W. Dodge Corporation. As these two general types of construction consume nearly all of the gypsum building products, their total floor area affords a reasonable basis for comparison. The sales of gypsum lath and wallboard by the selected companies represent approximately 90 and 95 percent respectively of the total annual sales of these products in the United States. The total tonnages of all calcined

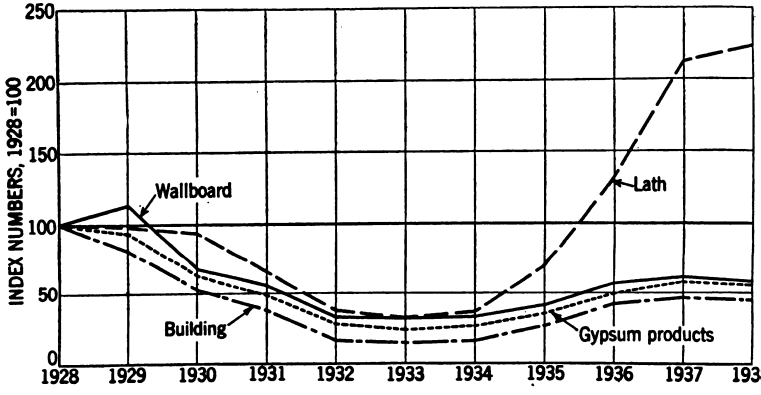

FIGURE 1.—Sales (square feet) of gypsum lath and wallboard by selected companies compared with total sales (short tons) of all calcined gypsum building products and total floor area (square feet) of residential and nonresidential building, 1928-38. Index numbers on building computed from F. W. Dodge Corporation data.

building products for 1937 and 1938 were adjusted for canvass changes so as to be comparable with preceding years.

The growing preference for gypsum lath over other types in the late twenties is shown clearly by the resistance in volume of sales of this product to the rapid decline in building activity after 1928. From 1931 to 1934 construction was virtually stagnant, and sales of lath followed the general trend of building. Beginning with 1935 gypsum lath became increasingly popular, and the volume of sales advanced rapidly. Thus, in 1938, when the total floor area of residential and nonresidential building was less than one-half the 1928 figure, the volume of sales of gypsum lath was 2¼ times greater than in 1928. The gain in 1938 over 1937 was smaller than that for the 2 preceding years but was accomplished despite a general decline in the volumes (measured as square feet for lath and wallboard, and short tons for plasters) of all other types of gypsum building products sold.

The great increase in sales of gypsum lath during 1935 and 1936 apparently resulted from a strong natural demand for lath, as the new price series of the Bureau of Labor Statistics shows that it developed without appreciable price reductions. The average wholesale price

Digitized by Google

(f. o. b. cars at destination) for standard ⅜-inch gypsum lath from 1928 to 1936 ranged between $17.18 and $18.19 per thousand square feet. A reduction to $15.87 per thousand square feet undoubtedly aided the expansion in lath sales during 1937, and a further drop in price to $15.23 per thousand square feet in 1938 was an added stimulus.

In contrast to the sales of gypsum lath, trend lines of the sales of wallboard and all gypsum building products have followed closely that of building. The great expansion in sales of lath would be expected to exert a greater influence on the total tonnage of all calcined building products than is shown in figure 1. Its failure to do so probably is caused by several factors. The first is that the quantity unit applied to lath is the square foot, and this unit is more accurate than the gross tonnages of lath, which represent mere estimates by the producers. Thus errors may be introduced in the change from one unit to another. The second is that the growing practice of using thinner plaster coats on gypsum lath than on the other types reduces for a given area the quantity of base-coat and ready-sanded plasters used and thus tends to counteract the increase in weight of lath sold. A third factor is the small but growing use of prefabricated finished wall surfaces, such as sheet-metal partitions, wood paneling, fiberboards, and plywood. This practice reduces the total wall area of building that normally requires the application of plasters and may have reduced consumption of gypsum plasters to such an extent as to counterbalance the increased weight of lath sold.

## RECENT DEVELOPMENTS

In the latter part of 1938, construction was started on two new gypsum-processing plants, one in Georgia and the other in Florida. They will utilize imported crude rock. During the year three independent one-plant companies, one each in Kansas, New York, and Utah, were merged with large multiple-plant companies. Operations ceased at the New York plant, which was dismantled immediately after it was purchased. In Illinois a plant using crude byproduct gypsum was closed permanently. A large producer of building materials entered the gypsum industry during the year, gaining control of an independent company in Ohio and obtaining an excess-capacity agreement with one of the principal gypsum producers.

Fresh interest was aroused in the drying and grinding of crude gypsum as a single operation when a hammer-type mill designed for this purpose was installed in one of the new processing plants under construction in the Southeast. It is understood that at least one producing company is experimenting with the drying, grinding, and calcining of gypsum as a single operation in a hammer-type mill. This process would eliminate two of the three steps that are necessary with the conventional equipment of gypsum-processing plants.

An outstanding development during 1938 was the introduction of a patented machine that will perforate gypsum lath by punching the holes through a single thickness of board. The machine, which operates continuously, is said to yield the best results when perforating lath directly before the cutting knife. If the operation is as successful as reported for the first installations, the standard method of bundling the lath and drilling the holes with a battery of augers probably will be replaced within a short time.

Results of a comprehensive study [1] of the heats of hydration and the transitions of the various forms of calcium sulfate were published by the Bureau of Standards. Investigations [2] by the same organization on the suitability of several types of lath as plaster bases and on the methods of plaster application are of interest to gypsum producers.

The Bureau of Mines published a description [3] of the occurrence, mining, and processing of gypsum in the United States. The report includes general information on anhydrite, which is closely related to gypsum.

## FOREIGN TRADE [4]

*Imports.*—The bulk of the imports of gypsum consists of crude rock, which enters the United States at certain New England, Middle Atlantic, Florida, and California ports. Although this material has a low average value per ton ($0.98 c. i. f. shipping port), such large quantities are imported that its total value comprised 93 percent of the total value of gypsum imports in 1938. Approximately 90 percent of the crude tonnage imported is processed into finished calcined-gypsum products at plants on tidewater near centers of consumption. Of the remaining tonnage, slightly more than half is ground and sold as agricultural gypsum, and the balance is consumed chiefly as retarder for portland cement.

The total value (c. i. f. shipping port) of gypsum imports during 1938 declined nearly 14 percent compared with 1937. All classes exhibited decreases of varying proportions except calcined, which increased slightly in tonnage and decreased in value. Crude gypsum imported during 1938 decreased 12 percent in quantity and 10 percent in value from 1937. Of the tonnage of crude material imported in 1938, tidewater quarries in Nova Scotia and New Brunswick, Canada, furnished 94 percent, and nearly all of the remainder came from San Marcos Island, Baja California, Mexico. The small tonnage from Italy evidently was composed largely of blocks of alabaster, which is used for carving art objects. The following tables show imports of gypsum and gypsum products in recent years.

*Gypsum imported for consumption in the United States, 1934–38*

| Year | Crude | | Ground | | Calcined | | Other manufactures n. e. s. | Keene's cement | | Total value |

*Exports.*—The total value of all gypsum and gypsum products exported from the United States in 1938 increased slightly over that in 1937. The following table shows that decreased shipments of raw gypsum and gypsum board were more than balanced by increases in the other classes of gypsum products exported.

*Gypsum and gypsum products exported from the United States, 1934–38*

| Year | Crude, crushed, or ground | | Plasterboard and wallboard | | Plaster, calcined, and manufactures | | Other manufactures, n. e. s. | Total value |

[1] Includes "Other manufactures, n. e. s."
[2] Not separately classified previous to 1937; included with "Plaster, calcined, and manufactures."
[3] Data not available; value reported as follows: "Crude, crushed, calcined, or ground," $107,732; "Plasterboard, wallboard, plaster, and manufactures, n. e. s.," $148,171.

The formation [5] of a Government-controlled company to produce gypsum board at Riga, Latvia, is of interest to the export trade. This plant, with an average guaranteed capacity of 1,500,000 square feet of board per year, is said to be the first of its kind in continental Europe. The entire production is to be exported.

## WORLD PRODUCTION

The following table shows the world output of crude gypsum from 1934 to 1938, inclusive, insofar as data are available. The leading producing countries, in probable order of importance, are the United States, France, United Kingdom, Canada, Germany, and the U. S. S. R.

# LIME

By Forrest T. Moyer and A. T. Coons

## SUMMARY OUTLINE

| | Page |
|---|---|
| Summary | 1189 |
| Salient statistics | 1190 |
| Production | 1191 |
| Production by States | 1192 |
| Hydrated lime | 1192 |
| Shipments | 1193 |
| Total shipments | 1193 |
| Hydrated lime | 1197 |
| Consumption by uses | 1198 |
| Agricultural lime and other liming materials | 1198 |
| Consumption by uses—Continued. | |
| Building lime | 1199 |
| Chemical lime | 1199 |
| Hydrated lime | 1202 |
| Size of plants | 1202 |
| Trends in principal uses | 1202 |
| New developments | 1204 |
| Foreign trade | 1205 |
| Imports | 1205 |
| Exports | 1206 |

The total quantity of lime (quick and hydrated) sold or used in the United States in 1938 was 19 percent lower than in 1937. Activity, which corresponded closely with average business conditions throughout the country, was depressed during the first half of the year but improved greatly in all branches of the industry during the latter half. However, these gains were insufficient to compensate for the earlier losses. The decrease in sales was accompanied by a slight decline in prices of nearly all types of lime. Sales of hydrated lime held up considerably better than those of quicklime, which fell 23 percent below 1937.

As reported by the operators, wages remained at approximately the same level as in 1937, although small local increases were noted. Labor difficulties, of which the most serious closed several large plants in the Middle West for nearly 6 months, occurred in scattered localities.

Because demand for all types of lime was low during the early months, total sales by general groups of uses in 1938 reflect the varying degrees of improvement that occurred in the consuming industries later in the year. The downtrend in building construction was among the first to be reversed, and activity in this industry increased steadily after the first quarter of the year. Dollar volume of contracts awarded for residential building, as reported by the F. W. Dodge Corporation, was nearly trebled from February to August and remained at a high level through December. Increased building of residences was aided to a large extent by the liberal mortgage-insurance policy of the Federal Housing Administration, which transacted a record volume of business. Likewise, the value of nonresidential building at the close of the year was nearly three times as great as it was in February. The subsidized-housing program of the Federal Government (United States Housing Authority), which was barely under way at the end of 1938, will be an important factor in the building industry during the first half of 1939. Despite the increase in contracts awarded, sales

Digitized by Google

of building lime in 1938 were 10 percent below 1937. The failure of lime to keep pace with the increase in building is doubtless due partly to the fact that many contracts awarded toward the close of the year did not reach the actual construction stage until early in 1939. Furthermore, there is always a lag of 1 to 3 months between the time of contract award and the purchase of lime.

In close accord with the 11-percent decline in the total cash farm income in 1938, sales of agricultural lime in 1938 were 10 percent below those in 1937. Both lime and limestone are used on agricultural land, but the claim is made that lime, particularly in hydrated form, affords a closer control of acidity or alkalinity in the soil than unburned stone.

*Salient statistics of the lime industry in the United States, 1937–38*

| | 1937 | 1938 | Percent of change in 1938 |
|---|---|---|---|
| Lime sold or used by producers: | | | |
| Total lime: | | | |
| Short tons | 4,124,165 | 3,346,954 | −18.8 |
| Value | $30,091,168 | $24,137,638 | −19.8 |
| Per ton | $7.30 | $7.21 | −1.2 |
| Hydrated lime (included in total): | | | |
| Short tons | 1,301,333 | 1,169,804 | −10.1 |
| Value | $10,344,470 | $9,111,575 | −11.9 |
| Per ton | $7.95 | $7.79 | −2.0 |
| By uses: | | | |
| For building: | | | |
| Short tons | 948,553 | 854,461 | −9.9 |
| Value | $8,212,995 | $7,163,165 | −12.8 |
| Per ton | $8.66 | $8.38 | −3.2 |
| For agriculture: | | | |
| Short tons | 406,462 | 364,312 | −10.4 |
| Value | $2,738,433 | $2,376,108 | −13.2 |
| Per ton | $6.74 | $6.52 | −3.3 |
| For chemical uses (excluding dead-burned dolomite): | | | |
| Short tons | 2,151,444 | 1,761,555 | −18.1 |
| Value | $13,921,907 | $11,503,010 | −17.4 |
| Per ton | $6.47 | $6.53 | +.9 |
| Dead-burned dolomite: | | | |
| Short tons | 617,706 | 366,626 | −40.6 |
| Value | $5,217,833 | $3,095,355 | −40.7 |
| Per ton | $8.45 | $8.44 | −.1 |
| Imports for consumption: | | | |
| Quicklime and hydrated lime: | | | |
| Short tons | 8,788 | 6,818 | −22.4 |
| Value | $90,605 | $66,203 | −26.9 |
| Per ton | $10.31 | $9.71 | −5.8 |
| Dead-burned dolomite: | | | |
| Short tons | 9,083 | 2,875 | −68.3 |
| Value | $231,084 | $67,340 | −70.9 |
| Per ton | $25.44 | $23.42 | −7.9 |
| Exports (lime): | | | |
| Short tons | 11,300 | 13,222 | +17.0 |
| Value | $122,895 | $121,662 | −1.0 |
| Per ton | $10.88 | $9.20 | −15.4 |

Chemical uses of lime, as grouped by the Bureau of Mines, consumed 389,889 short tons less in 1938 than in 1937, a decline of 18 percent. Sales to the principal consuming industries of this group generally decreased from those in 1937 in varying proportions. An increase was noted only in sugar refining, which consumes a relatively small tonnage. The quantity of metallurgical lime sold or used showed the greatest decline—29 percent below 1937. This drop in consumption resulted chiefly from the low average levels of activity

Digitized by Google

in the steel and copper industries. Nearly three-fourths of the total tonnage of metallurgical lime is used in making steel ingots, production of which in 1938, according to Federal Reserve Board data, was only 67 percent of the 1923–25 annual average contrasted with 119 percent in 1937. Approximately half of the remaining tonnage is consumed in the flotation of copper ores, and the total quantity of such ores treated in 1938 was lower than in 1937.

Sales of lime to the paper industry, the second largest consumer of chemical-grade lime, were 10 percent below 1937, reflecting a corresponding decrease in the total volume of all major types of paper produced. A substantial decline in plate-glass and glass-container production in 1938 was accompanied by a decrease of 24 percent in the quantity of lime used in glass manufacture.

In 1938 sales of dead-burned dolomite, for the first time since 1932, failed to show a gain over the preceding year and were 41 percent below the record volume of 1937. The tonnage decrease of this material, which is used mainly for open-hearth refractories, resulted from the low percentage of capacity at which steel plants operated during the year. Moreover, as implied by the record consumption in 1937, the furnaces probably were in good condition and required a minimum of repairs to the refractory linings. In this chapter data on dead-burned dolomite do not include the entire consumption in the United States, as some steel companies calcine dolomite purchased raw or obtained from their own quarries. Such tonnages, recorded in the chapter on Stone in this volume, decreased 54 percent from 1937.

For the first year since 1919 the total value of lime exports in 1938 nearly balanced the total value of imports for consumption. However, the export-import trade represents only a small fraction of the total lime business.

## PRODUCTION

The recovery of the lime industry from the economic depression of the early 1930's progressed steadily from 1932 to 1937, total sales in each year increasing over those of the preceding year in both quantity and value. In 1938, however, this upward movement was halted, and lime consumption fell below that of 1936. Data covering recent years are given in the following table.

*Lime sold or used by producers in the United States, 1934–38*

| Year | Plants in operation | Short tons [1] | Value [2] | |
|---|---|---|---|---|
| | | | Total [1] | Average |
| 1934 | 324 | 2,397,087 | $17,164,024 | $7.16 |
| 1935 | 301 | 2,987,133 | 21,748,655 | 7.28 |
| 1936 | 301 | 3,749,383 | 26,933,719 | 7.18 |
| 1937 | 314 | 4,124,165 | 30,091,168 | 7.30 |
| 1938 | 321 | 3,346,954 | 24,137,638 | 7.21 |

[1] Includes lime used by producers (captive tonnage) as follows—1934: 129,290 short tons valued at $671,864; 1935: 143,716 tons, $750,155; 1936: 224,693 tons, $1,179,820; 1937: 270,192 tons, $1,388,052; 1938: 168,245 tons, $985,003.

[2] Value given represents value of bulk lime f. o. b. at point of shipment and does not include cost of barrel or package.

Digitized by Google

*Production by States.*—As the following table shows, production of lime in most States was lower in 1938 than in 1937; the largest declines occurred in Missouri and West Virginia. Increased output was noted for several States, the largest being in Indiana, Maryland, and Tennessee. The production of lime in 1938 in the three leading States—Ohio, Pennsylvania, and Missouri—comprised 50 percent of the total output of the country.

*Hydrated lime.*—Despite a drop in the average value per ton, the quantity of hydrated lime sold or used in 1938 declined 10 percent from 1937. This was the first year since 1934 in which sales were less than in the preceding year. The accompanying table presents data from 1934 to 1938, inclusive.

Digitized by Google

*Hydrated lime sold or used by producers in the United States, 1934–38*

| Year | Plants in operation | Short tons | Value | |
|---|---|---|---|---|
| | | | Total | Average |
| 1934 | 165 | 829,430 | $6,324,623 | $7.63 |
| 1935 | 167 | 1,005,619 | 7,939,513 | 7.90 |
| 1936 | 168 | 1,225,829 | 9,529,743 | 7.77 |
| 1937 | 170 | 1,301,333 | 10,344,470 | 7.95 |
| 1938 | 165 | 1,169,804 | 9,111,575 | 7.79 |

As the following table indicates, production of hydrated lime in 1938 was smaller than in 1937 in most States. The sharp decline of 24 percent in Missouri probably was due to a prolonged strike, which closed several large plants. Production increased in only a few States, California showing the largest proportional gain—19 percent. Ohio and Pennsylvania continued to be the leading producing States, and their combined output was 49 percent of the total for the country.

*Hydrated lime sold or used by producers in the United States, 1937–38, by States*

| State | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| Alabama | 23,884 | $167,292 | 26,266 | $190,567 |

## SHIPMENTS

*Total shipments.*—Sales, shipments, and supplies of lime available for consumption by States in continental United States are given in the accompanying table. Reshipments beyond the original destinations from the producing plants are disregarded. Pennsylvania, with its great variety of industries, ranks first by a large margin in apparent consumption of both quick and hydrated lime. Other States, in order of tonnage of quicklime consumed in 1938, were Ohio, West Virginia, and Illinois, and of hydrated lime, New York, Ohio, and New Jersey. A greater tonnage of lime was shipped from Ohio than from any other State, and more lime was shipped into New York for consumption than into any other State.

[1] Based on latest figures of Bureau of Census.
[2] Included under "Undistributed."
[3] Includes 12,458 short tons of lime exported or unspecified by producers as to destination.

The origin and destination of hydrated, quick, and total lime shipments for 1937 and 1938, by groups of States that comprise approximate freight zones, are listed in the following tables. These data do not include a small quantity of lime (about 1 percent of the total) consisting of Hawaiian and Puerto Rican production, foreign shipments, and tonnage for which distribution is not recorded. Reshipments beyond the original destinations from the producing plants are not considered.

The following table shows the relatively small quantities of lime shipped from continental United States to various island Territories.

*Lime shipped to noncontiguous Territories of the United States, 1937–38*

| Territory | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| American Samoa | | | (1) | $7 |
| Hawaii | 666 | $11,212 | 1,770 | 26,071 |
| Puerto Rico | 1,024 | 13,638 | 895 | 9,643 |
| Virgin Islands | 188 | 3,947 | 97 | 1,902 |
| Wake Island | (1) | 3 | | |
| | 1,878 | 28,800 | 2,762 | 37,623 |

[1] Less than 1 ton.

*Hydrated lime.*—The following table shows total shipments of hydrated lime into various groups of States in 1937 and 1938. The largest apparent consumption is in the Middle Atlantic States, with their densely populated industrial centers. Distribution of hydrated lime from Ohio plants to the same groups of States are shown separately in the table.

*Shipments of hydrated lime from plants in continental United States and in Ohio, 1937–38, by destinations*

## CONSUMPTION BY USES

The quantity and value of lime (quick and hydrated) utilized in the principal consuming industries are given in the following table. Chemical lime (including metallurgical) constitutes slightly more than half of the total tonnage sold or used.

*Lime sold or used by producers in the United States, 1937–38, by uses*

| Use | 1937 | | | | 1938 | | | |
|---|---|---|---|---|---|---|---|---|
| | Quantity | | Value | | Quantity | | Value | |
| | Percent of total | Short tons | Total | Average | Percent of total | Short tons | Total | Average |
| Agricultural | 9.8 | 406,462 | $2,738,433 | $6.74 | 10.9 | 364,312 | $2,376,108 | $6.52 |

| Hydrated lime (included in above totals) | 31.6 | 1,301,333 | 10,344,470 | 7.95 | 35.0 | 1,169,804 | 9,111,575 | 7.79 |

[1] Details of distribution shown in a following table.
[2] Includes lime used by producers (captive tonnage) as follows—1937: 270,192 short tons, valued at $1,388,052; 1938: 168,245 tons, $985,003.

*Agricultural lime and other liming materials.*—In recent years sales of lime for agricultural uses have followed closely fluctuations in cash farm income. Scientific appraisal of the advantages of all types of fertilizers and soil conditioners should encourage a wider use of lime. The accompanying table presents data on several liming agents and their effective lime content.

*Agricultural lime and other liming materials sold or used by producers in the United States, 1937–38, by kinds*

| Kind | 1937 | | | | 1938 | | | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | | Value | | Short tons | | Value | |
| | Gross | Effective lime content [1] | Total | Average | Gross | Effective lime content [1] | Total | Average |
| Lime from limestone: | | | | | | | | |
| Quicklime | 140,425 | 118,000 | $762,496 | $5.43 | 126,539 | 106,000 | $666,550 | $5.27 |
| Hydrated | 266,037 | 186,000 | 1,975,937 | 7.43 | 237,773 | 166,000 | 1,709,558 | 7.19 |
| Lime from oyster shells [2] | 13,098 | 10,700 | 89,119 | 6.80 | (3) | (3) | (3) | (3) |
| Oyster shells (crushed) [2] | 76,966 | 33,000 | 273,500 | 3.55 | (3) | (3) | (3) | (3) |
| Limestone | 5,004,930 | 2,152,000 | 6,454,695 | 1.29 | 4,367,410 | 1,878,000 | 5,637,485 | 1.29 |
| Calcareous marl | 46,650 | 20,000 | 59,775 | 1.28 | 23,572 | 10,100 | 40,270 | 1.71 |

*Building lime.*—Consumption of building lime in 1938 compared favorably with that of other building materials, although sales were lower than in 1937.

*Chemical lime.*—The wide use of lime in the chemical industries may be inferred from a recently published table [1] that lists the relative frequency with which mineral raw materials are used in the actual manufacture (not purification, treatment, etc.) of 150 important industrial chemicals. In the table, limestone, which in many chemical processes is calcined to the oxide (quicklime) before actual consumption, has a relative use frequency of 63 and was surpassed by only five substances, water, air, coal, sulfur, and salt. The quantity and value of lime sold or used in 1937 and 1938 for minor chemical applications that are designated "Other uses" in a previous table were as follows:

*Chemical lime sold or used by producers in the United States for "Other uses," 1937-38*

| Use | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| Acid neutralization | 3,437 | $32,819 | 5,075 | $45,080 |
| Alkali works (ammonia, soda, potash) | 13,756 | 69,809 | 12,369 | 68,556 |
| Bleach (liquid and powder) | 9,141 | 57,775 | 16,844 | 112,245 |
| Calcium carbide | 109,755 | 565,309 | 116,173 | 615,682 |
| Chromate and bichromate | 11,216 | 66,238 | 13,824 | 84,538 |
| Coke and gas manufacture (gas purification and plant byproducts) | 21,989 | 143,656 | 14,844 | 96,599 |
| Food products | 10,664 | 63,744 | 6,199 | 36,860 |
| Gelatin (edible) | 4,988 | 41,743 | 5,925 | 43,280 |
| Glue | 7,882 | 57,482 | 6,456 | 43,241 |
| Insecticides (spraying materials) | 45,967 | 358,271 | 43,921 | 350,054 |
| Magnesia works | 10,091 | 65,908 | 18,830 | 135,311 |
| Oil and fat manufacture | 20,271 | 133,116 | 13,792 | 93,313 |
| Oil refining | 10,161 | 92,873 | 6,914 | 74,772 |
| Paint (calcimine, whitewash, varnish, etc.) | 27,240 | 176,447 | 12,589 | 90,866 |
| Polishing and buffing | 3,549 | 78,563 | 2,307 | 58,508 |
| Rubber | 1,732 | 13,742 | 1,330 | 9,399 |
| Salt refining | 5,369 | 28,774 | 4,317 | 24,973 |
| Sand-lime brick | 20,746 | 140,817 | 14,417 | 94,350 |
| Sanitation | 3,977 | 25,719 | 8,693 | 58,482 |
| Silica brick and slag brick | 12,887 | 96,154 | 5,733 | 42,132 |
| Soap | 7,362 | 36,060 | 6,162 | 32,611 |
| Wood distillation | 6,029 | 43,126 | 1,012 | 7,385 |
| Miscellaneous uses [1] | 31,363 | 208,453 | 20,044 | 139,738 |
| Use unspecified | 146,924 | 1,063,400 | 112,832 | 779,011 |
| | 546,496 | 3,659,998 | 470,602 | 3,136,986 |

[1] Includes lime used in the manufacture of acetic acid, alcohol, bituminous road materials, beer, calcium acetate, calcium arsenate, calcium carbonate, calcium chloride, calcium phosphate, chemicals (not specified), corn products, dairy products, depilatories, dyes, flour, helium gas, ice, indigo, iron oxide, lubricants, nicotine, oxalic acid, oxygen, retarder, sulfur, sulfuric acid, and textiles.

The consumption of dead-burned dolomite declined greatly in 1938. Sales represented only 11 percent of the total lime business in 1938 contrasted with 15 percent in 1937.

Distribution of lime sales by States and uses in 1938 are shown in the accompanying table.

## SIZE OF PLANTS

The following table presents data on the number of companies and plants grouped according to the quantity of lime produced in selected years. Total production of the various groups is also shown. Noteworthy features are the increase in the number of active plants producing between 25,000 and 49,999 short tons from 26 in 1928 to 35 in 1938, also the increase in the proportion of the total output made by plants producing 10,000 to 49,999 tons annually.

*Lime (including dead-burned dolomite) sold or used by producers in the United States, 1928, 1933, and 1938, by companies and plants grouped according to size*

| Size group (short tons per year) | 1928 | | | 1933 | | | 1938 | | |
|---|---|---|---|---|---|---|---|---|---|
| | Companies | Plants | Short tons | Companies | Plants | Short tons | Companies | Plants | Short tons |
| Less than 1,000 | 152 | 152 | 37,556 | 143 | 143 | 39,374 | 98 | 98 | 27,931 |
| 1,000 to 4,999 | 74 | 74 | 186,218 | 70 | 70 | 169,760 | 77 | 79 | 179,875 |

## TRENDS IN PRINCIPAL USES

Sales of chemical lime (including metallurgical) and dead-burned dolomite comprised 64 percent of the total sales of lime in 1938 compared with 67 percent in 1937. This decline, which was caused chiefly by the large decrease in sales of dead-burned dolomite, modifies the trend lines materially, as shown in figure 1. Conditions in 1938 indicated the formation of trends similar to those of the early 1920's when sales of building lime formed approximately half of the total lime sales compared with about one-fourth of the total in recent years. However, as the drastic decrease in sales of metallurgical lime and

Digitized by Google

dead-burned dolomite in 1938 resulted from the low rate of operation in the steel industry, the pronounced change in the relative magnitude

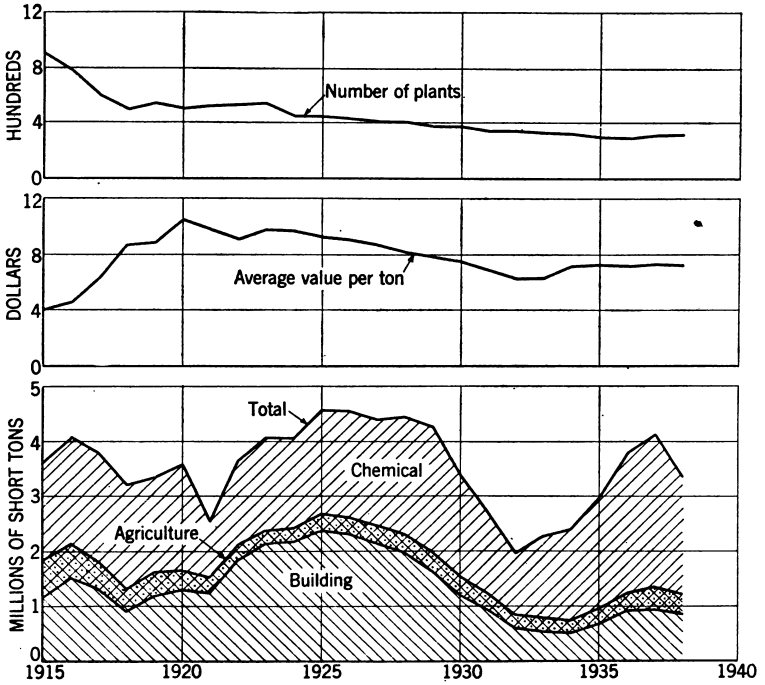

FIGURE 1.—Trends in the number of active plants, average value per ton, and principal uses of lime, 1915–38.

of sales of chemical and building lime in 1938 compared with recent preceding years is believed to be temporary only and not significant in the long-time trend.

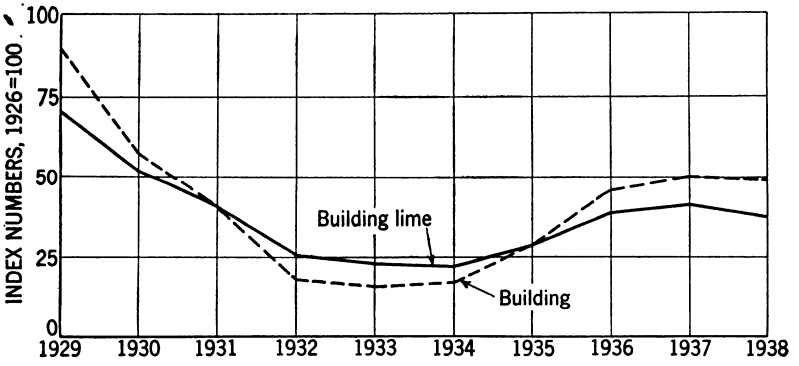

FIGURE 2.—Building-lime (quick and hydrated) sales compared with total floor area of residential and nonresidential building, 1929–38. Index numbers on building computed from F. W. Dodge Corporation data.

Figure 2 shows graphically the total quantity of lime consumed in building construction compared with the floor area of residential and nonresidential building during the 10-year period, 1929–38.

Metallurgical lime is used chiefly for open-hearth flux in the steel industry, but minor quantities are consumed in the flotation of metallic ores, cyanidation of gold ores, smelting, and wire drawing. The relatively large use of metallurgical lime compared with steel-ingot production since 1933, as shown in figure 3, was due to an increase in the quantity of lime used in flotation and cyanidation. The disproportional rise in sales of dead-burned dolomite since 1932 compared with steel-ingot production resulted from the increasing substitution of this low-priced refractory material for higher-priced refractories in the steel industry.

## NEW DEVELOPMENTS

*Specifications.*—A tentative specification (C141–38T) for hydraulic hydrated lime for structural uses has been issued by the American Society for Testing Materials. Two types, high-calcium (containing

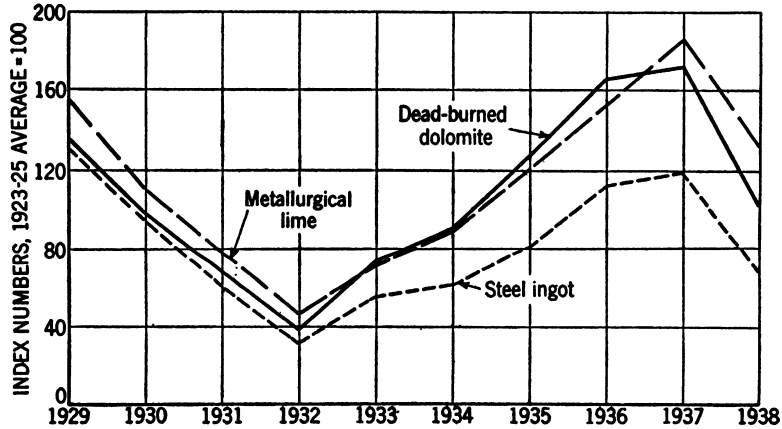

FIGURE 3.—Metallurgical lime and dead-burned dolomite sales compared with steel-ingot production, 1929–38. Index numbers on steel ingots computed by Federal Reserve Board from data of American Iron and Steel Institute.

not more than 5 percent MgO) and magnesium (containing more than 5 percent MgO) hydraulic hydrated limes, are covered.

The Federal Specifications Executive Committee has also issued a specification (SS–L–361) that covers the requirements for hydraulic hydrated lime purchased by Federal agencies.[2]

The National Lime Association after lengthy investigations has issued specifications covering lime and lime-cement mortars for use in unit masonry. These mortars contain more lime than the present-day masonry mortars and are said to afford a better bond with the building units and more weather-resistant construction.

*Plants.*—Only a few entirely new lime plants, all of relatively small capacity, were constructed during the year. Existing equipment was improved or replaced at numerous plants in all sections of the country. Capacity was increased at several plants by the addition of new kilns. Several companies substituted pulverized coal for producer gas as fuel for rotary kilns. The replacement is said to yield

[2] Copies of Federal specifications may be obtained upon application accompanied by money order, coupon, or cash, to the Superintendent of Documents, Government Printing Office, Washington, D. C. American Society for Testing Materials specifications may be obtained from the office of the secretary of the society, 260 South Broad Street, Philadelphia, Pa.

Digitized by Google

better heat control with more efficient calcination and a reduction in costs. The reported [3] successful use of pulverized coal as fuel for shaft kilns is of interest to operators. This fuel replaced natural gas and has been used for the past several years in three kilns, of which two operated on lump limestone and one on spalls down to 1-inch size. Although the performance of the kilns varies, the average results show increased capacity and efficiency.

The successful operation [4] of a plant to manufacture carbon dioxide gas, liquid and solid (dry ice), from kiln gases of an existing lime plant was an outstanding development of the year. Capacity is reported as 15 tons of dry ice per day, which is obtained by processing the gases from one of three shaft kilns, each of which has a daily capacity of 15 tons of lime.

In 1938 a record enrollment of 35 lime plants participated in the safety contest [5] sponsored by the National Lime Association and the Bureau of Mines. The combined accident-frequency and accident-severity rates of the enrolled plants increased over 1937 and were respectively 25.2 per million man-hours of exposure and 4.3 days of disability per thousand man-hours in 1938.

*Research.*—Results of investigations by Conley [6] on the rate of calcination of cylinders of limestone, dolomite, and magnesite show that calcination proceeds at a fairly uniform rate, which is directly proportional to the exposed surface and the temperature.

## FOREIGN TRADE [7]

*Imports.*—Imports of lime, most of which is brought into Washington and California, were lower in 1938 than in 1937. The quantity and value of imports of dead-burned dolomite decreased considerably from 1937. The following tables present data on lime and dead-burned dolomite imported for consumption.

*Lime imported for consumption in the United States, 1934–38*

| Year | Hydrated lime [1] | | Other lime [1] | | Dead-burned dolomite [2] | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 923 | $8,872 | 8,309 | $74,447 | 6,473 | $166,912 | 15,705 | $250,231 |
| 1935 | 1,030 | 10,571 | 3,413 | 36,032 | 7,519 | 189,714 | 11,962 | 236,317 |

# CLAYS: KAOLIN (CHINA CLAY AND PAPER CLAY), BALL CLAY, FIRE CLAY, BENTONITE, FULLER'S EARTH (BLEACHING CLAYS), AND MISCELLANEOUS CLAY

By PAUL M. TYLER and R. W. METCALF [1]

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General summary | 1207 | Miscellaneous clay | 1218 |
| Salient statistics | 1208 | Heavy-clay products | 1219 |
| China clay or kaolin | 1208 | Prices | 1219 |
| Ball clay | 1210 | Consumption and uses | 1219 |
| Fire clay | 1210 | Technology | 1221 |
| Bentonite | 1213 | New plants | 1223 |
| Fuller's earth | 1215 | | |

In 1938, notwithstanding further displacement of foreign by domestic clays, the quantity of china clay sold or used by producers in the United States dropped 19 percent, ball clay 22 percent, and fire clay 48 percent from the 1937 levels, representing the results of recession in the consuming industries. A decline of 24 percent in the output of bleaching clay (fuller's earth), however, is attributed largely to the increasing use of substitutes. Bentonite sales were about the same as during the preceding year, reduced requirement in some consuming lines being offset by increased use in others. The heavy-clay-products industries—raw material for which is used chiefly at the locality where it is obtained and hence is not included in Bureau of Mines production figures—fell off slightly. Although building-contract awards in 1938 were substantially greater than those reported for 1937, the improvement was confined to the last few months, and deliveries of many kinds of building materials, including brick and tile, did not share the upturn until after the close of the year.

Under the Anglo-American Trade Agreement, the duty on kaolin or china clay was reduced, effective January 1, 1939, from $2.50 to $1.75 per long ton, the duty on fuller's earth was cut from $1.50 to $1 per ton, and that on "wrought or manufactured" fuller's earth was dropped from $3.25 to $2 per ton. Other reductions under this agreement included the duties on brick (reduced from 25 percent to 15 percent) and on floor, wall, and quarry tiles (various rates). The second trade agreement between the United States and Canada, also effective January 1, 1939, resulted in reductions on fire brick (now 12½ percent) on common brick and other kinds of undecorated brick (now $1 per 1,000); it also halved the duties on bentonite.

## CHINA CLAY OR KAOLIN

Sales of domestic kaolin or china clay dropped in 1938 to 595,054 short tons valued at $4,740,880—substantially below the 1937 record of 732,282 tons worth $5,349,636, but almost equaling the 1936 total and well above that of any other preceding year. Imports, on the other hand, were far less in 1938 than in any previous year since 1897, amounting to only 84,180 short tons valued at $753,858 (43 percent less in quantity than in 1937). The change in the duty on china clay, effective January 1, 1939, was not announced early enough in the year to encourage postponing purchases to take advantage of the reduction, but consumers of English clays had overbought in 1937. The potters especially had to curtail operations more than did many of the consumers of American clays, which have not yet succeeded in obtaining wide adoption in plants making hotel china and certain kinds of sanitary ware and electrical porcelain.

The heaviest declines in domestic production in 1938 were in Georgia and South Carolina, which supply most of the paper and rubber clays. Output in California virtually matched the 1937 record; and even in Pennsylvania, which has a more diversified market, the decrease was moderate.

The average price of domestic sales in 1938 was $7.97 a short ton, or substantially higher than the average of $7.31 for the preceding year. Some producers accepted lower prices for their paper filler clays, and possibly for their rubber clays, but these reductions were more than offset by the higher averages reported by several producers who have notably improved the quality of their products. The main

Digitized by Google

reason for the increase in the average, however, was the relatively great reduction in shipments of low-priced refractory kaolins from Georgia compared with those of the more expensive kinds.

Quotations throughout 1938 generally remained about where they were at the end of 1937. Paper filler clays, produced principally in Georgia, ranged in price mostly from $6 to $8 a ton, f. o. b. mines, whereas coating clays ran from this range upward to $20 or more a ton. The average prices, as reported by producers, were approximately $8 and $12 for filler and coating clays, respectively, in 1938 compared with $7.08 and $10.74 in 1937. Rubber clays in 1938 ranged from $7.50 to $11 a ton, and the average price rose above $9.75, f. o. b. Georgia or South Carolina shipping points, compared with $8.80 in 1937—again denoting an increased proportion of highly processed clays. Notwithstanding the fact that North Carolina potting clays are so much better prepared now than ever before, they are still quotable around $15 a ton f. o. b. mines.

Price schedules for English clays were virtually unchanged in 1938. However, charter rates for cargo shipments from Cornish ports, after rising to 19s. or more in 1937, ranged throughout most of 1938 at 15s. to 15s. 6d. a long ton and ocean rates on German clays fell from $4.75 to $4.50 and later to $3.75 a metric ton.

## BALL CLAY

Shipments of ball clay from domestic mines totaled 94,968 short tons valued at $739,691 in 1938 compared with 121,470 tons and $890,705 during the preceding year. The 1937 figures, however, were an all-time record, and the 1938 shipments were well above the averages for earlier years when general business was much more active. Separate statistics showing imports of ball clays are not available, but tonnage receipts under the general classification of "common blue and ball clay," which ordinarily consists principally of English ball clays, were 46 percent less than in 1937. American ball clays, which are produced almost wholly in Kentucky and Tennessee, are about $4 a ton cheaper than English clays of similar quality and are being accepted by American potters and other consumers, many of whom have come around to the opinion that they are as good or better than the foreign clays that at one time were universally preferred.

Eighty percent of the shipments of domestic ball clay in 1938 were used in the manufacture of white pottery or cream-color ware, 17 percent in high-grade tile, and the remaining 3 percent in a variety of products, including architectural terra cotta, linoleum, paints, refractory brick, enamels, and miscellaneous articles.

*Ball clay sold by producers in the United States, 1936–38*

## FIRE CLAY

Owing to inactivity in the refractories industries and listless demand from metallurgical plants, shipments of fire clay from domestic mines were less in 1938 than in any previous year since 1934. The total shipments of fire clay and stoneware clay were 1,458,941 short tons valued at $4,060,160 in 1938 compared with 2,785,344 tons worth $7,180,938 in 1937, 48 percent less in quantity and 43 percent less in value.

Gross-Almerode glass-pot clay is a German clay that formerly was used extensively in this country in the manufacture of pots and tanks in which glass was melted; clays of this type burn dense at a relatively low temperature and are relatively free from impurities that would color glass. In 1938 the imports of these glass-pot clays aggregated only 205 short tons valued at $2,470 compared with 1,737 tons and $21,645 in 1937 and 2,145 tons and $26,852 in 1936, the first year for

Digitized by Google

which separate statistics are available. In earlier years, however, they were much larger.

A well-known British observer has reported [2] that glass-pot makers in the United States are divided in opinion as to whether the best pots are made from 100 percent American clay or from mixtures of European and American clays. The pots themselves have been displaced to a large degree by tank furnaces, and for tank-furnace linings sillimanite and electrically cast products have tended to displace fire-clay blocks.

Imports of miscellaneous clays, including Klingenberg and certain other German fire clays as well as smaller amounts of clay of various kinds from other countries, decreased to 5,683 tons valued at $83,384 in 1938 compared with 15,558 tons valued at $203,383 in 1937 and 18,034 tons valued at $281,592 in 1936. In this group are included such specialized importations as pipe clays, pencil clays, emery wheel clays, enamel clays (other than kaolin and ball clay), etc. The total imports of fire clay, although not reported separately, probably have averaged in recent years only about one-third as much as the exports.

Exports of fire clay in 1938 were 55,764 tons worth $389,042 as against 77,330 tons worth $529,661 during the preceding year. Canada always has been the principal foreign market for American fire clay, taking about 80 percent of the total exports.

Workable deposits of fire clay are distributed widely throughout the United States, but over 75 percent of all domestic sales have been produced in Pennsylvania, Missouri, Ohio, California, Kentucky, Illinois, and New Jersey. Plastic fire clay and a smaller amount of the hard type, known as flint clay, occur in the coal measures of the Middle West and are particularly abundant in Pennsylvania, Ohio, Maryland, and Kentucky. Plastic clays, laid down before the Carboniferous and unassociated with coal, are mined in New Jersey. Refractory clays of Tertiary and other later geologic ages are worked in Texas, Mississippi, California, Washington, and Colorado. Diaspore and so-called burley clays (high-alumina) are mined only in the north central Ozark region of Missouri.

Anticipating refractory clay requirements of metallurgical industries that may be attracted by cheap electrical power from Bonneville Dam, the Oregon State Department of Geology and Mineral Industries in cooperation with the University of Washington and the Bureau of Mines, United States Department of the Interior, conducted an investigation indicating that, contrary to former opinion, western Oregon has large deposits of good fire clay and can supply the future requirements of electrometallurgical and other industries in the Pacific Northwest.[3]

For several years the Bureau of Mines has deemed it advisable to include stoneware clays in the same classification with fire clay. Stoneware clays, which are characteristically somewhat less refractory than fire clay and have a long vitrification range, are produced principally in Ohio and Illinois and are used not only for stoneware but also for yellow ware, artware, sanitary ware, and architectural terra cotta. They have the properties of a kaolin and a ball clay

Digitized by Google

combined but usually contain an excess of silica and a little iron. A portion of the iron appears as specks in the fired ware; this is not objectionable for ordinary stoneware but makes the clay unsuitable for whiteware. Proper beneficiation, however, may make it possible to eliminate the iron so that the material may be used for dinnerware.

The average price of domestic fire clay and stoneware clay f. o. b. mines in 1938 was $2.78 a ton, compared with an average of only $2.48 a ton as recently as 1936. These averages show a definite rising trend. About 1900 this composite value was generally around $1 a ton, by 1914 it had risen to $1.50, and after exceeding $3 during the post-war boom (but later declining to $2.50 a ton) it seems once more to be rising to $3. Part of this increase may be attributed to more preparation, yielding a better product, but it is likely that mining costs have advanced, increased mechanization being offset by exhaustion of the more easily worked deposits.

The principal use of fire clay is for making fire-clay brick, and large quantities of ground fire clay also are used in fire-clay mortars for laying firebrick and for various refractory purposes in foundries and steel works. The leading outlets outside refractories are pottery and stoneware, saggers and wads for firing pottery, and architectural terra cotta. The production of fire-clay brick in the United States had begun to decline slightly even before 1929, when the output was 938 million brick, valued at $36,169,000. This compares with a top value of $53,416,000 in 1920 and a volume peak of 1,304 million with a value of $42,502,000 in 1917. In 1932 volume dropped to 217 million, worth $7,611,000. Following a recovery to 711 million, valued at $33,730,843 in 1937, the output undoubtedly declined sharply in 1938. Sales of refractory products normally are the first to feel the effects of a business recession and among the last to pick up again during recovery.

## BENTONITE

Development of even more new uses for bentonite nearly balanced a drop in consumption in certain other industries, with the result that the output in 1938 was 192,183 short tons valued at $1,373,182, compared with 194,768 tons worth $1,500,758 in 1937. No longer than a dozen years ago, the output of this extraordinary material was almost negligible.

Small quantities of bentonite have been imported from Canada for a decade or more, but since 1930 (when separate statistics first became available) the only imports of "unwrought" bentonite have been $49 worth imported from Germany in 1932 and 1 ton valued at $5 from Italy in 1938. Imports of "wrought" bentonite likewise have been insignificant since 1930, comprising only $70 worth in 1936 (chiefly German), 1 ton valued at $30 from Canada in 1937, and 6 tons valued at $223 from Italy in 1938. The 1938 receipts from Italy are of special interest, inasmuch as they came from the newly discovered deposits of white bentonite that is not as abundant in this country as the other types. Under the trade agreement with Canada, the duty on crude bentonite was reduced from $1.50 to $0.75 a long ton and that on "wrought or manufactured" material from $3.25 to $1.625.

Exports of bentonite are included in the statistical classification "all other clays." Type 1 ("Wyoming" type) bentonite is shipped from the United States all over the world, and an examination of the high unit values for exports under this classification from the Los Angeles customs district suggests that activated earths, made by processing Type 2 (nonswelling) bentonite, likewise may be included in this same classification.

Possibly the most interesting development in the industry during 1938 was the reported discovery by Dr. Ernst A. Hauser, Massachusetts Institute of Technology chemistry professor, that bentonite films may be processed to afford a successful substitute for mica in various important uses. This new product, which is expected to come on the market in at least a small way during 1939, has been called Alsifilm, emphasizing its hydrous-aluminum-silicate composition. According to Dr. Hauser, possibly the first important commercial outlet may be as insulating tapes for wrapping wires and telephone cables. These films, however, are said to be fireproof, waterproof, chemically inert, unaffected by mold, unattractive to insects, transparent, flexible, and fairly tough. Consequently, their employment for a variety of uses where dielectric properties are not needed is suggested. It is claimed that they take ink readily and thus may prove useful for permanent documents; moreover, that they can be made of any desired thickness like built-up mica or sheets of paper glued together, only without needing any additional binder. Other uses proposed are to line food or beverage containers and to wrap butter, tobacco, cigarettes, and other perishable or oily products. Ordinarily flexible, or even creaseproof, the material may be modified in appearance and properties by incorporating various pigments and fillers.

In talking with a member of the Bureau of Mines staff, Doctor Hauser explained the formation of these films as due to the attachment of colloidal clay particles end to end in strings or tiny filaments that mat like organic fibers do in the manufacture of ordinary paper

Digitized by Google

or felt. Although produced experimentally at first in an ultra-centrifuge, the films were later manufactured by various methods. At the moment extrusion of the moist jelly seems the most practical method of commercial production because it can be embodied readily in a continuous process whereby Doctor Hauser believes the material probably can be manufactured at a cost of only a few cents a pound. The hardening of the films to make them impervious to liquids is a separate treatment about which very little has been published. In addition to various types of bentonite, other sources of hydrous aluminum silicates have been utilized experimentally. The product from ordinary Wyoming bentonite is not colorless; in fact, it looks like oiled paper. By using a white bentonite, low in iron, however, the product can be made almost perfectly transparent.

Under the cooperative agreement between the Massachusetts Institute of Technology and the Research Corporation (137 Newbury Street, Boston, Mass.), the latter undertakes the patent protection and commercial development under a policy of making the discovery as widely available as possible. Profits from all the various enterprises conducted by the Research Corporation are reinvested in research.

Consumption of bentonite in foreign countries has not paced that in the United States, owing to its high price abroad. Domestic bentonite has been exported all over the world, but only in rather small quantities. Large, scattered bodies of bentonite have been reported in Germany, but German bentonite differs greatly in many physical properties from the American bentonites, because it contains calcium as the exchangeable base instead of sodium; some German clays, however, are being treated artificially to exchange the calcium for sodium.

European interest has been stimulated recently by the discovery of several new deposits. The U. S. S. R. is said to have large deposits of bentonite, and Italy has opened up what was reported to be an important group of deposits on the Island of Ponza, one of the Pontine group off the west coast between Rome and Naples. Samples of this new Italian material are of excellent quality and are of the swelling type, though differing from Wyoming bentonite in that they are virtually pure white. Trial shipments have been made to the United States, and already the Italians have used it in steel molding sands. Several important deposits have been found in the Western Provinces of Canada, and in 1938 the Canadian output jumped to 1,136 tons from 163 tons in 1937. Occurrences have been reported also in Japan, British India, France, Mexico, China, and New Zealand.

Bentonite prices have remained nominally $8 a ton in bulk and $10 in bags for the crude clay (dried and crushed), f. o. b. Wyoming mines, whereas selected air-floated material is quoted at $25 a ton at Chicago. As reported to the Bureau of Mines, crude bentonite ranges in price from $4 to $8 a ton, according to quality and locality. The milled clay generally sells in South Dakota at $7.50 to $8 a ton, f. o. b. cars, and in other parts of the country material prepared for oil-well drilling varies in price upward to $20.

## FULLER'S EARTH

Confirming the recent trend toward use of smaller quantities but better qualities of bleaching clays, Bureau of Mines figures for fuller's earth consumption in the United States show a 24-percent drop in 1938, when domestic production of fuller's earth or natural bleaching clays fell to 170,852 short tons valued at $1,707,869 compared with 226,165 tons worth $2,296,094 in 1937 and 230,814 tons worth $2,264,978 in 1936. Imports—which have been unimportant in recent years, averaging less than 2 percent of annual consumption during the last decade—also decreased further in 1938, while exports increased, though not importantly.

The predominant use of fuller's earth is in oil refining, and shipments of fuller's earth from domestic mines paralleled expansion of the petroleum industry for several decades, increasing steadily from an annual average of 40,000 tons before the World War to a peak of 335,644 tons in 1930. Following a temporary setback in the early years of the general business depression, petroleum refining resumed its strong uptrend, whereas the use of fuller's earth failed to increase after 1932. The failure of fuller's earth consumption to equal the greater activity in petroleum refining is due in part to a relative reduction in the output of lubricants, the branch of the refining industry that uses the largest proportion of bleaching clay. But new methods of processing that require much smaller additions of fuller's earth, and the substitution of other bleaching materials—first, activated earths and, in 1938, bauxite—are even more depressing factors.

Figure 1 compares fuller's earth consumption with the index of petroleum refining and with the production of lubricants. The declining proportion of lubricating oils in relation to gasoline consumption in automobiles is attributed to an increase in the average interval between oil changes. Formerly it was common practice to change oil every 500 miles; but now some car manufacturers recommend changes only every 2,000 or 5,000 miles, and some truck operators never change their oil.

In recent years about 10 percent of the domestic output of fuller's earth has been used in the refining of vegetable oils and animal fats, a

Digitized by Google

general increase in the tonnage being attributable to the growth of these industries and to gradual displacement of imported by domestic earths. Formerly English earth was considered indispensable; it filtered well, with minimum retention of oil, and, more important, all available domestic clays imparted an unpleasant taste to the oil. With the opening up of new deposits, the use of domestic clays for treating edible products increased until 1938, when shipments to vegetable and animal oil refineries also decreased sharply, probably because of competition from artificially activated or acid-treated earths.

The United States is by far the largest producer of fuller's earth and normally exports as much as 5 percent of its domestic production. Whereas imports consist of relatively costly earths for use principally in refining edible oils and fats, exports comprise less expensive earths for use in mineral-oil refining. Exports of fuller's earth are not re-

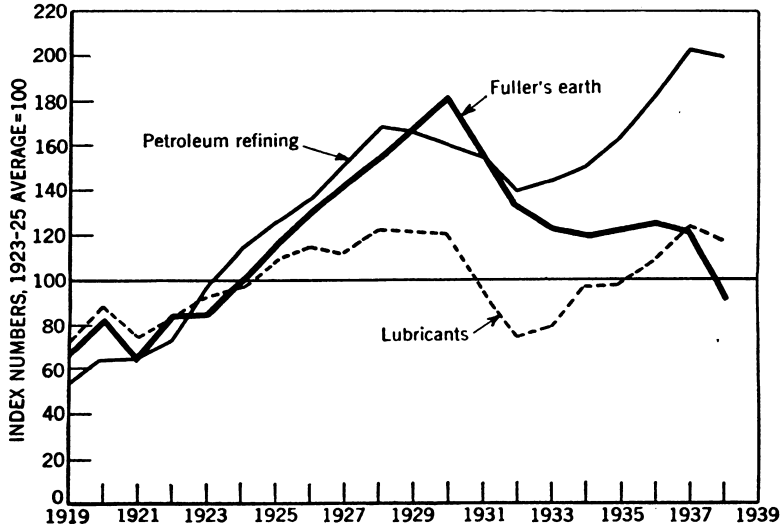

FIGURE 1.—Consumption of fuller's earth compared with petroleum refining activity (Federal Reserve Board index) and production of lubricants, 1919–38.

ported separately in the official statistics of the United States, but since 1923 domestic producers have reported their foreign shipments to the Bureau of Mines. In 1938 such shipments aggregated 10,046 short tons valued at $81,175 ($8.08 per ton) compared with 8,104 tons, worth $70,985 ($8.76 per ton) in 1937, 6,118 tons, worth $56,180 ($9.18 per ton) in 1936 and a maximum quantity of 21,264 tons in 1929, when the average value was $12.15 a ton. In 1927, when 12,287 tons were exported, the average value was $15.61.

Canada has been the most important single export market for fuller's earth in recent years, but shipments have been made to oil refineries all over the world. However, most countries having sizeable petroleum industries are able to obtain suitable bleaching earths locally, and international trade in fuller's earth is confined largely to the exports of American earth to mineral-oil refineries and of English earth to refineries treating edible oils and animal fats. Germany, which has large deposits of fuller's earth in Bavaria, produces a clay that is much less efficient than English or American earths in its natural state but is converted by hydrochloric acid treatment into an activated product

Digitized by Google

that has a bleaching power two or three times as great. Somewhat similar activated material is made in California and Mississippi from bentonites having virtually no decolorizing power in the raw state. It is commonly claimed that the greatly improved domestic material now equals the German product in efficiency. Imports of the latter have diminished greatly, and the American activated earth is exported in substantial quantities.

Recently the United States Court of Customs and Patent Appeals upheld a decision that the German product (trade name "Tonsil") was dutiable at ¼ cent a pound and 30 percent ad valorem as "clays or earths artificially activated with acid or other material" rather than at $3.25 a ton as "fuller's earth, wrought or manufactured." The court avoided a decision on whether the product was a bentonitic clay and based its finding upon the evidence that the activity of the earth actually was increased by the acid treatment.[4]

The average value of the fuller's earth produced in the United States in 1938 was $10 a ton, f. o. b. mines, compared with $10.15 in 1937, a recent low of $9.28 in 1933, and a high of $19.51 in 1920. Prices vary according to particle size, fine material suitable only for contact use being relatively cheap. The Engineering and Mining Journal quotations for Georgia or Florida earth, f. o. b. mines, have remained unchanged for several years at $14.50 per short ton for 30- to 60-mesh, $14 per ton for 15- to 30-mesh, $10 for 200-mesh up, and $7 for 100-mesh up.

Experiments with bauxite begun in 1937, for decolorizing oils by percolation processes, were extended in 1938; at least three companies are offering it as a substitute for fuller's earth—the Porocel Corporation (260 South Broad Street, Philadelphia, Pa.), the Floridin Co. (Warren, Pa.), and Max B. Miller & Co., Inc. (50 Church Street, New York, N. Y.). It is significant that all these companies (or their affiliates) also produce fuller's earth and the Porocel Corporation is jointly interested also in the production of activated earth. The new process seems applicable only to oils of the paraffinic type and those that can be made paraffinic but is being used in at least 10 refineries in Pennsylvania and Mid-Continent oil fields. The main advantage of bauxite is that it can be revivified indefinitely, whereas fuller's earth loses its efficiency and must be discarded after 20 burnings.[5]

On the other hand, new uses for fuller's earth may be developing in water purification. According to Weir,[6] the regular use of 20 pounds of clay costing about 10 cents per million gallons, with alum applications, has increased the efficiency of water treatment in Atlanta, Ga., 10 to 30 percent. At Chester, Pa., 43 pounds of clay costing 35 cents were used successfully for treating oily trade waste waters. The clay produces a heavy floc that reduces putrescence, odors, and even coliform bacteria. The United States has some 10,000 water-treatment plants, supplying about 65 million people with 5 billion gallons of water a day, thus indicating a daily demand of 50 to 100 tons of clay or roughly 10 percent of the quantity of fuller's earth now being consumed. However, about 300 tons of activated carbon are consumed daily in removing unpleasant odors and tastes from water; and if clay could be used instead of carbon, or even as an adjunct

Digitized by Google

thereto, the potential demand might be of the order of 1 million tons or more yearly (as it takes 10 to 50 times as much clay as carbon).

The adsorptive power of fuller's earth of the Georgia-Florida type (montmorillonite) itself is being increased 20 percent by an extrusion treatment. The moistened clay is pugged (kneaded) and then forced through slots, very much as common brick are formed in an auger machine. This process not only makes a better product but permits virtually complete recovery of all the clay in granular form suitable for percolation methods of oil refining, thereby enhancing its value further.

## MISCELLANEOUS CLAY

Clay utilized for making common brick, sewer pipe, and other clay products ordinarily is not included in Bureau of Mines statistics. It comprises probably 90 percent of all clay dug; but little of it is merchant clay, as most of it is fabricated at integrated plants situated close to the pits. The bulk of the "miscellaneous clays" reported by the Bureau of Mines, however, falls in this category, which also includes some of the clay used as a blending material for portland cement and such rotary oil-well-drilling muds as do not fall in the bentonite class. Virtually the entire miscellaneous group is composed of clays worth not more than about $1 a ton, although a few specialties, such as slip clay, are valued much higher. A large part of the California drilling mud formerly classed as bentonite is now known to be of a different character and is classified as miscellaneous clay.

## HEAVY-CLAY PRODUCTS

In February 1938 shipments of common brick turned upward after declining steadily for 9 months, but the rise was moderate and total shipments probably were much less than in 1937. Employment in brick, tile, and terra cotta works in the United States confirmed the apparent uptrend, the 1938 pattern being almost the reverse of that of the preceding year. Stocks increased in 1937 but were much reduced in 1938, contributing further to the more optimistic viewpoint at the year end. As is shown by the usual indexes based upon 1923–25 averages, however, these industries still lag behind other building-material industries and far behind the recovery in general factory employment and production.

The Bureau of the Census reports that in 1937 the value of all clay products made in the United States, exclusive of pottery and nonclay refractories, was $159,853,658 compared with $136,249,772 in 1936. For common brick alone the value rose from $30,108,170 to $34,009,775 and the quantity from 2,967 million in 1936 to 3,253 million in 1937. In 1925, the peak year, the production of common brick was 7,562 million worth $88,551,400.

## PRICES

Available quotations for the several kinds of clays and fuller's earth have been summarized already in this chapter under the respective subheads. The average valuations of the specific groups as reported by producers are summarized in the following table:

*Average values per short ton of various kinds of clay sold by producers in the United States, 1930–34 (average) and 1935–38*

| Year | Kaolin | | Ball clay | Slip clay | Fire clay and stoneware clay | Bentonite | Fuller's earth |
|---|---|---|---|---|---|---|---|
| | United States | South Carolina | | | | | |
| 1930–34 (average) | $6.44 | $6.83 | $7.16 | $6.83 | $2.59 | $8.13 | $10.62 |
| 1935 | 7.19 | 7.57 | 6.55 | 5.99 | 2.64 | 6.65 | 9.79 |
| 1936 | 7.10 | 7.53 | 6.87 | 6.37 | 2.48 | 7.69 | 9.81 |
| 1937 | 7.31 | 8.16 | 7.33 | 6.55 | 2.58 | 7.71 | 10.15 |
| 1938 | 7.97 | 8.75 | 7.79 | 6.27 | 2.78 | 7.15 | 10.06 |

## CONSUMPTION AND USES

The real magnitude of the industries of the United States that depend on clay is not revealed by Bureau of Mines figures. Not only do they exclude the raw clay used in making common brick, hollow building blocks, and other heavy-clay products but also, even for plants where the tonnages and value of raw clay is reported, they fail to show the value of the fired clay articles that are the real products sold.

Moreover, some of the clays used locally for pottery making may not be reported at all, not even in respect to their estimated value as raw clay. In California, for example, a wide variety of fire clays and miscellaneous clays, as well as kaolin, can be grouped in the general classification of pottery clays, being used in the manufacture of red and brown earthenware; china and sanitary ware; flower pots; floor, faience, and ornamental tiling; architectural terra cotta; and similar

Digitized by Google

products. As pointed out by State Mineralogist Bradley,[7] of California, the output of "pottery clay" in that State alone in 1936 was 382,823 tons, worth only $646,920, whereas products manufactured from this clay were worth $9,886,209.

The accompanying table, which shows sales of specified domestic clays by kinds and uses in 1937, continues a series begun in 1921. Since it does not include imported clays and since domestic clays have displaced imported clays more and more, the data for different years are not accurately indicative of consumption or even strictly comparable. This is especially true in respect to the total consumption of china clay in hotel china, sanitary ware, electrical porcelain, and coating paper, the industries in which English clays have been chiefly used. Minor displacements have occurred in other lines.

Sales of fuller's earth are shown in a separate table because the uses other than for refining oils and fats, although increasing, are relatively small.

*Clay (excluding fuller's earth) sold by producers in the United States in 1938, by kinds and uses, in short tons*

| Use | Kaolin | Ball clay | Fire clay and stoneware clay | Bentonite | Miscellaneous clay including slip clay | Total |

## TECHNOLOGY

No longer content with even the best clay that nature provides, consumers are now getting processed clays whose properties not only are definitely controlled but also can be modified within wide limits. There is growing evidence to show that whiteness, opacity, and other characteristics of a good coating clay depend to an astonishing degree on fineness. Two American companies are employing Bird's solid-bowl continuous centrifuge, with or without electrophoretic attachment, to effect exact control of particle size. A coating clay made by this process contains no particles over 2 microns in size, and any desired fractionation can be accomplished with precision. Certain paper-filling clays that ordinarily would be worth $7 a ton yield, by this low-cost treatment, a fair proportion of these superquality clays worth $15 to $80 a ton, the coarser fractions still being usable as filler clays. Bleaching, too, has become a fine art that can be accomplished with scientific exactitude. Instead of merely neutralizing cream tints with bluing, the offending iron can be removed in large part from many clays by wet treatment with hydrosulfite or a combination of zinc and sulfurous acid. Other clays are gray due to carbon or organic matter removable sometimes by heating (though this may ruin the structure of a paper clay), or possibly by froth flotation. Of equal importance to paper makers are the newly developed methods for determining quickly the quality of a given coating material. Using the color analyzer built by Prof. Arthur C. Hardy of the Massachusetts Institute of Technology, reflectance of a given sample can be plotted directly over the whole spectrum in 5 minutes. Properly processed

Digitized by Google

Georgia clays show an average reflectance of close to 90 percent of the standard magnesia button for virtually all wave lengths within the visible range. No means has yet been discovered commercially to eliminate the depression in the shorter wave-lengths due to titanium, but the sharp valley due to absorption by iron oxides can be smoothed out almost completely by suitable beneficiation.

National Bureau of Standards tests [8] on 45 experimental papers with different filling and sizing material show that for the same pulp furnish, the smoothness values were about the same for precipitated calcium carbonate and clay, and less for natural calcium carbonates, titanium dioxide pigments, and zinc sulfide pigments. With respect to their influence on the oil penetrability of the paper, the order in decreasing rapidity of penetration was: Precipitated calcium carbonate, natural calcium carbonate, zinc sulfide pigments, titanium dioxide pigments, and clay. The fillers ranked in this latter order also in respect to the degree to which they increase air permeability.

Another National Bureau of Standards report [9] relates to pressures for extruding clays and late trends in clay products manufacture have been reviewed comprehensively by Hursh.[10]

Processing of Illinois weathered glacial clay to provide good-quality oil-well drilling mud, bond clays, and bleaching clays is reported [11] as offering commercial possibilities.

Everyone knows what clay is, yet no one has been able to define it satisfactorily. Not only do most clays comprise a variety of minerals, but the same minerals do not always exhibit the same properties. Plasticity, generally cited as the chief characteristic of clays, is almost absent from some kaolins whose composition, mineralogically and chemically, corresponds exactly with what once was assumed as being "typical clay substance." On the other hand, other substances that no one would think of calling clay become plastic when suitably handled and worked. Reporting a lecture by Sir William Bragg, Searle [12] has reviewed the present knowledge of the structure of clays, with special emphasis upon new developments in X-ray examination. On this basis clays are divided into only two groups, (1) those allied to halloysite, kaolinite, nacrite, and dickite; and (2) those allied to pyrophyllite—including montmorillonite, beidellite, bentonite, and fuller's earth (which differ in metal content). In both complex silicates and clays, he says, the atoms (oriented at the apexes of tetrahedra) form a pattern of rectangular units, and the various sheets or layers must fit perfectly in combination even though they may differ slightly in separate existence. The suggested structures explain the colloidal properties of the smallest clay particles, the relatively enormous effect of minute additions of alkalis or acids to clay pastes and suspensions, and they go far to explain variations in plasticity. The "cause of plasticity," according to Sir William Bragg, is the entry of water molecules into the unit cells. The effect of this entry on the clay lattice is to increase the *c* axis without altering the *a* and *b* axes, opening it up like an accordion. This water acts as a lubricant,

allows the clay particles to move easily without loss of shape or mass.

The peculiar ability of some clays to absorb water molecules and to arrange them in successive sheets in the layerlike structure of the clay crystal itself also may explain the property of "base exchange" of some derivatives of montmorillonite clays (zeolites). In spite of their complexity, the aluminosilicates can be classed in three simple groups, according to whether the structure is (1) fibrous, (2) micaceous, or (3) framework. The first (compare fibrous zeolites) has rigid molecular binding in only one direction, like rope strands that can be pulled apart easily in two directions. The second group has rigid binding in two directions but not in the third; its members split easily into thin sheets, frequently spontaneously in liquids. Mica, talc, the bentonites, pyrophyllite, and even kaolinite have been classed as micaceous minerals, and their platy cleavage results naturally from this structure. The third group has rigid binding in all directions. It does not follow, however, that the framework is always compact and impermeable; in fact it may be so open and porous that ions flow in and out, as in certain zeolites. All three types of structure are found in clays, shales, and surface soils; but in the finer grain sizes, micaceous types predominate and tend to determine the behavior of the mixture. Ross and Kerr distinguish four groups of clay minerals (1) kaolin group, (2) montmorillonite (bentonite) group, (3) potassium-bearing clays, and (4) a more evasive group occurring in shales. However, real structural data, as outlined by Sir William Bragg, appear to be available only for the first group.

A new concept for the transition of colloidal clay sols to gels has been prepared by the discoverer of Alsifilm, the mica substitute.[13]

## NEW PLANTS

New construction trends during 1938 have been summarized as follows: [14]

The Louisiana Boganite Corporation recently completed a new plant at Bogalusa, La., for the production of drilling mud and filter and bleaching clays. The equipment in this modern new plant includes a 40-ft. rotary drier, a Williams hammer-mill, a Raymond 5-roller high-side mill with a Whizzer separator, a Raymond flash-drying system, etc.

A new plant with two Gruendler hammer-mills was built by the Georgia Coating Clay Co. at Macon, Ga. Louisville driers and Raymond equipment were also installed in this plant, and in the new plants of the Sgoda Corporation at Phillips, Ga., and the Champion Paper & Fiber Co., at Sandersville, Ga. A new oil-well clay plant with a Raymond mill was built by the Beaumont Cement Sales Corporation at Villa Platte, Tex. Quality Earths, Thomasville, Ala., built a new plant. New equipment in the plant of the Filtrol Corporation, Jackson, Miss., includes a Research Corporation Cottrell precipitator, a Raymond mill, a Jeffrey hammer-mill, and other equipment. The California Kaolin Co. plans to erect a $10,000 plant at Lone Pine, Cal. The Earthen Products Co., Houston, Tex., completed a $25,000 reequipment and expansion program.

In Minerals Yearbook 1938 (p. 1122) it was recorded that the new plant of the Tennessee Bleaching Clay Corporation at Paris, Tenn., had been burned in 1937; it was rebuilt subsequently and operated in 1938.

# ABRASIVE MATERIALS

By BERTRAND L. JOHNSON and M. SCHAUBLE

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1225 | Natural silicate abrasives | 1232 |
| Salient statistics | 1225 | Pumice and pumicite | 1232 |
| Natural silica abrasives | 1226 | Garnet | 1234 |
| Diatomite | 1226 | Natural alumina abrasives | 1236 |
| Tripoli | 1227 | Corundum | 1236 |
| Quartz | 1228 | Emery | 1236 |
| Ground sand and sandstone | 1229 | Natural carbon abrasives | 1237 |
| Abrasive sand | 1230 | Diamond | 1237 |
| Special silica stone products | 1230 | Artificial abrasives | 1238 |
| Grindstones and pulpstones | 1230 | Miscellaneous abrasive materials | 1239 |
| Oilstones and related products | 1231 | Foreign trade | 1239 |
| Millstones | 1231 | | |
| Flint lining and grinding pebbles | 1232 | | |

The abrasive materials industry followed general decline in activity that characterized 1938. The aggregate values of both natural and artificial abrasives sold in 1938 were considerably less than in 1937, although trends in the values of individual abrasives were mixed. There were marked declines in the values of diatomite, tripoli, ground sand and sandstone, grindstones and pulpstones, millstones, garnet, and emery in 1938 compared with 1937. Increased values were shown, however, for quartz, oilstones and related products, and pumice and pumicite. The value of imports of abrasives was off 36 percent from 1937 and the value of exports, 7 percent.

*Salient statistics of abrasives industries in the United States, 1937–38*

| | 1937 | 1938 | Percent of change in 1938 |
|---|---|---|---|
| Domestic production (sold or used by producers): | | | |

[1] Average for 1936–38, not included in totals given; Bureau of Mines not at liberty to publish annual figures.
[2] Bureau of Mines not at liberty to publish figures.
[3] Excludes value of diatomite and flint lining and grinding pebbles, which the Bureau of Mines is not at liberty to publish.
[4] Includes some material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.

Digitized by Google

This chapter includes most of the materials used principally for abrasive purposes, although those mentioned later under "Miscellaneous abrasive materials" are not included in the statistics given herein. Several commodities listed as abrasive materials for which statistical data are given also have important nonabrasive uses.

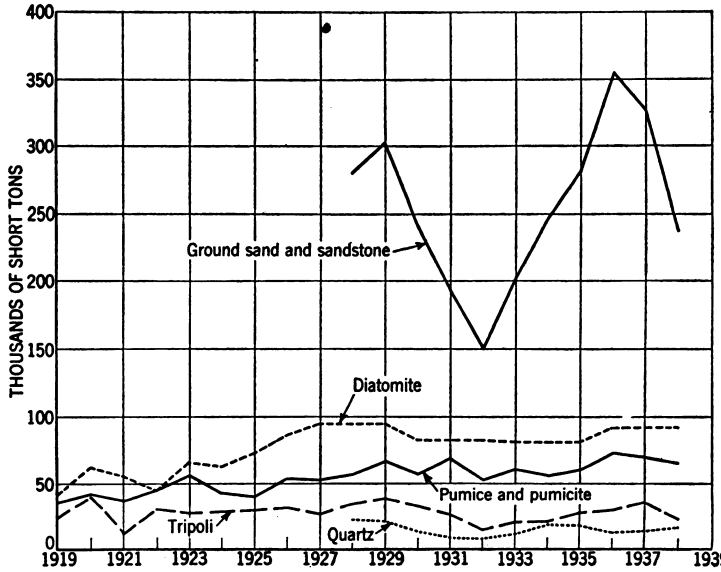

FIGURE 1.—Trends in production of diatomite, tripoli, pumice and pumicite, quartz, and ground sand and sandstone, 1919–38.

A general review of the abrasives industry in 1937 by Eardley-Wilmot [1] appeared in 1938.

## NATURAL SILICA ABRASIVES

*Diatomite.*—The Bureau of Mines has not been at liberty to publish annual production figures on diatomite since 1926. Production data for 3-year periods, however, may be shown, and the averages for the 3-year periods since 1926 are plotted in figure 1. The trend in sales of diatomite in the immediate predepression years was upward, reaching an all-time peak in 1929. Total sales for the 3-year period 1927–29 were 286,426 short tons. Sales in the next two periods declined, but in 1936–38 they recovered to 279,645 tons—not quite the predepression level. Sales in 1938 were considerably less than those in 1937, but even in 1937 they did not reach the level of the all-time peak year 1929 or of 1930.

The greater part of the domestic production of diatomite comes from the Western States. California continued in 1938 to be the chief source, but sales were reported also in other Western States (Idaho, Nevada, Oregon, and Washington), as well as in Florida and New York. The following table presents such data on diatomite sales from 1933 to 1938 as the Bureau of Mines may publish.

*Diatomite sold or used by producers in the United States, 1933–38* [1]

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1933<br>1934<br>1935 | 244,342 | $3,618,428 | 1936<br>1937<br>1938 | 279,645 | $4,377,353 |

[1] Bureau of Mines not at liberty to publish annual figures.

A review of the diatomite industry during 1937 appeared early in 1938.[2] The fresh-water diatomite deposits of the Pacific Coast region were described by Mulryan [3] in a recent publication. Deposits of fresh-water diatoms occur in commercial quantities in California, Oregon, Washington, Idaho, Nevada, and Arizona. In general they are associated with volcanic activity of late Tertiary or Pleistocene time. The deposits are roughly circular, with their maximum thickness at the center. Some of the older dry deposits are horizontal; others tilt as much as 50°. Deposits also are found in present-day lakes. Ordinarily these diatomite deposits are composed essentially of types of diatoms that produce the heavier powders, their uses being limited to polishes, fillers, admixtures, and insulation products. The chief exception is the Terrebonne deposit from which filtration powders are also produced.

*Tripoli.*—Sales of tripoli (including Pennsylvania rottenstone) in 1938—the lowest since 1934—decreased more than 12,000 tons from 1937 and reversed the rising trend from the 1934 low point through 1937. Sales in 1938 were only 22,188 short tons valued at $329,081. Tripoli was produced in Arkansas, California, Illinois, Missouri, Oklahoma, and Tennessee. The Missouri-Oklahoma and Illinois districts were the principal producing areas. Rottenstone was produced only in Pennsylvania. Figure 1 shows the trend of the industry in recent years. The following table gives the data for tripoli from 1934 to 1938.

*Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1934–38*

| Year | Illinois | | Other States [1] | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 7,417 | $119,418 | 13,112 | $209,938 | 20,529 | $329,356 |
| 1935 | 10,001 | 113,484 | 17,374 | 269,932 | 27,375 | 383,416 |
| 1936 | 10,981 | 138,063 | 17,506 | 253,815 | 28,487 | 391,878 |
| 1937 | 11,647 | 151,154 | 23,289 | 299,416 | 34,936 | 450,570 |
| 1938 | 8,141 | 117,107 | 14,047 | 211,974 | 22,188 | 329,081 |

[1] 1934: Arkansas, California, Georgia, Missouri, Oklahoma, Pennsylvania, and Tennessee; 1935: Arkansas, California, Georgia, Missouri, Oklahoma, and Pennsylvania; 1936: Arkansas, California, Missouri, Oklahoma, and Pennsylvania; 1937-38: Arkansas, California, Missouri, Oklahoma, Pennsylvania, and Tennessee.

Of the domestic tripoli sold in 1938, 36.5 percent was for abrasive uses, but in some years, such as 1936, as much as 60 percent has been so used. The second largest use has been for fillers, which took 8,363 tons in 1937 but only 5,584 tons (25 percent of the total) in 1938. The

following table gives the quantity and value of tripoli and rottenstone sold or used by producers and classified by them according to uses.

*Tripoli sold or used by producers in the United States in 1938, by uses*

| Use | Producers reporting | Short tons | Value | Percent of total | |
|---|---|---|---|---|---|
| | | | | Quantity | Value |
| Abrasives | 8 | 8,097 | $138,807 | 36.5 | 42.2 |
| Concrete admixture | 3 | 2,170 | 12,634 | 9.8 | 3.8 |
| Filler | 4 | 5,584 | 78,900 | 25.2 | 24.0 |
| Miscellaneous [1] | 5 | 6,337 | 98,740 | 28.5 | 30.0 |
| | [2] 10 | 22,188 | 329,081 | 100.0 | 100.0 |

[1] Includes tripoli used for filter block, foundry facing, and other unspecified uses.
[2] A producer reporting more than one use is counted only once in arriving at total.

The tripoli deposits of western Tennessee and Mississippi, characteristics of the tripoli, technology, and possible uses were described in a report [4] published early in 1938.

*Quartz.*—Sales of crude, crushed, and ground quartz from pegmatite dikes, veins, and quartzite beds were decidedly greater both in quantity and value in 1938 than in 1937. The quantity sold was greater than in any year since 1929. The average value per ton, however, fell from $5.08 in 1937 to $4.74 in 1938. Figure 1 shows the trend in sales of quartz in recent years. The greatest increase in tonnage was in crushed quartz, but the greatest increase in value was in the higher-priced ground quartz. Sales of ground quartz, although higher than in 1937, recovered little of their slump since the high sales of 1934. Massachusetts, Oregon, and Wisconsin produced quartz in 1938, in addition to the States that were productive in 1937.

Data on sales of quartz by kinds from 1934 to 1938 and by States from 1936 to 1938 are shown in the following tables.

*Quartz (crude, crushed, and ground)[1] sold or used by producers in the United States, 1934–38*

| Year | Crude | | Crushed | | Ground | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | [2] 4,447 | [2] $16,168 | (2) | (2) | 13,846 | $113,797 | 18,293 | $129,965 |
| 1935 | [2] 7,586 | [2] 26,807 | (2) | (2) | 9,592 | 84,977 | 17,178 | 111,784 |
| 1936 | [2] 6,281 | [2] 24,971 | (2) | (2) | 6,705 | 71,621 | 12,986 | 96,592 |
| 1937 | 3,252 | 10,096 | 5,891 | $24,652 | 3,869 | 31,293 | 13,012 | 66,041 |
| 1938 | 4,493 | 17,023 | 9,930 | 27,941 | 4,188 | 43,233 | 18,611 | 88,197 |

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.
[2] "Crushed" included under "Crude."

*Ground sand and sandstone.*—Both the quantity and value of sales of ground sand and sandstone declined sharply in 1938 from those in 1937. Sales totaled only 237,167 short tons valued at $1,425,445 in 1938 compared with 328,156 tons valued at $1,996,528 in 1937. The larger producing States are usually Illinois, New Jersey, Ohio, and Pennsylvania.

The following tables give the sales of ground sand and sandstone from 1934 to 1938 for the United States as a whole and in 1937 and 1938 for such States as can be shown.

*Ground sand and sandstone sold or used by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 248,026 | $1,392,173 | 1937 | 328,156 | $1,996,528 |
| 1935 | 281,665 | 1,678,295 | 1938 | 237,167 | 1,425,445 |
| 1936 | 356,423 | 2,146,464 | | | |

*Ground sand and sandstone sold or used by producers in the United States, 1937–38, by States*

| State | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| Illinois | 96,329 | $575,251 | 66,583 | $418,881 |
| Massachusetts | 2,613 | 12,448 | 1,234 | 4,102 |

Figure 1 shows the trend in production of ground sand and sandstone.

Digitized by Google

The quantities of ground sand and sandstone sold for different uses in 1938 and their total and average value per ton for each use are listed in the following table. Data for sales by uses from 1936 to 1938, inclusive, show that the "pottery, porcelain, and tile" industry is by far the leading market with the abrasive industry in second place in each of these 3 years. Other important uses are in foundry operations, in enamel manufacture, and as a filler.

*Ground sand and sandstone sold or used by producers in the United States in 1938, by uses*

| Use | Short tons | Value | |
|---|---|---|---|
| | | Total | Average per ton |
| Glass | 7,306 | $38,097 | $5.21 |
| Foundry | 22,413 | 134,158 | 5.99 |
| Pottery, porcelain, and tile | 93,790 | 631,592 | 6.73 |
| Enamel | 10,784 | 63,360 | 5.88 |
| Cleansing and scouring compound | 62,439 | 308,926 | 4.95 |
| Other abrasive use | 543 | 5,933 | 10.93 |
| Filler | 8,878 | 43,741 | 4.93 |
| Other | 31,014 | 199,638 | 6.44 |
| Total reported by uses | 237,167 | 1,425,445 | 6.01 |

*Abrasive sand.*—Abrasive sands are hard sands with a high percentage of silica. They include all natural sands used for abrasive purposes, such as sawing stone, grinding glass, making sandpaper, and sandblasting. Sales in recent years have followed the general industrial trend from a peak in 1929 to a low in 1932 and a recovery to 1,067,178 short tons valued at $1,440,736 in 1937. Statistics for 1938 and the relationships of abrasive sand to the rest of the sand and gravel industry are shown in the chapter on Sand and Gravel in this volume.

Schwalbe,[5] in an article in Glass Industry, describes the processing, at the River Rouge plant of the Ford Motor Co., of raw Manistee Beach sand from Lake Michigan and the continuous grading and classification of the grinding sand by grain size.

## SPECIAL SILICA STONE PRODUCTS

*Grindstones and pulpstones.*—The total value of grindstones and pulpstones sold by producers in the United States in 1938 ($240,006) was less than in any year since 1895, when only $205,768 worth was sold. The tonnage and value of grindstones sold in 1938 were lower than in any year since 1914 when they were first shown separately. The value of pulpstones sold in 1938 was less than in any year since 1932.

Natural grindstones were produced in northeastern Ohio and western West Virginia in 1938 and pulpstones in West Virginia and Washington.

[5] Schwalbe, F. G., Grading and Reclaiming Grinding Sand: Glass Ind., vol. 19, No. 6, June 1938, pp. 207–212.

Digitized by Google

The following table gives sales of these materials from 1934 to 1938, inclusive.

*Grindstones and pulpstones sold by producers in the United States, 1934–38*

| Year | Grindstones | | Pulpstones | | |
|---|---|---|---|---|---|
| | | | Quantity | | Value |
| | Short tons | Value | Pieces | Equivalent short tons | |
| 1934 | 9,781 | $285,603 | 760 | 2,849 | $177,631 |
| 1935 | 11,476 | 342,864 | 948 | 3,111 | 162,514 |
| 1936 | 10,703 | 334,363 | 685 | 2,472 | 163,634 |
| 1937 | 11,617 | 352,377 | 761 | 2,924 | 220,331 |
| 1938 | 4,653 | 149,019 | 417 | 1,553 | 90,987 |

*Oilstones and related products.*—The demand for sharpening stones of various types was markedly less in 1938 than in 1937; consequently, sales of oilstones and related products were lower than in 1936 and 1937, but remained above those of the depression years, 1931 to 1935. Several States helped meet the demand: Arkansas furnished novaculite for oilstones and whetstones; Indiana and Ohio sandstone for oilstones, scythestones, and whetstones; New Hampshire schist for scythestones; and Indiana fine-grained sandstones for manufacture into rubbing stones.

The following table shows the sales of oilstones and related products from 1934 to 1938.

*Oilstones and other whetstones, hones, scythestones, and rubbing stones sold by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 396 | $94,419 | 1937 | 810 | $112,841 |
| 1935 | 439 | 105,589 | 1938 | 511 | 130,277 |
| 1936 | 752 | 121,196 | | | |

*Millstones.*—The value of natural millstones sold in the United States in 1938 dropped to the lowest point reached in the 59 years for which the statistics of production of millstones have been recorded. This value, $3,743, was less than half that of sales in 1937. Sales in 1938 were confined to two States—New York with four producers and Virginia with two. American millstones have been made, for the most part, of quartz sandstones and conglomerates. As in recent years, production in 1938 was confined to millstones of these types—the "Esopus" stone from the Shawangunk conglomerate in Ulster County, N. Y., and the "Brush Mountain" fine-grained quartzite from Brush Mountain, Montgomery County, Va.

The following table gives the annual production data for natural millstones and related products from 1934 to 1938.

Digitized by Google

*Value of millstones, chasers, and dragstones sold by producers in the United States, 1934–38*

| Year | New York | | Other States[1] | | Total | |
|---|---|---|---|---|---|---|
| | Producers | Value | Producers | Value | Producers | Value |
| 1934 | 5 | $3,381 | 3 | $6,720 | 8 | $10,101 |
| 1935 | 8 | 4,645 | 3 | 4,885 | 11 | 9,530 |
| 1936 | 6 | 5,458 | 3 | 5,151 | 9 | 10,609 |
| 1937 | 6 | (2) | 2 | (2) | 8 | 8,305 |
| 1938 | 4 | (2) | 2 | (2) | 6 | 3,743 |

[1] 1934–35: North Carolina and Virginia; 1936–38: Virginia.
[2] Bureau of Mines not at liberty to publish figures.

*Flint lining and grinding pebbles.*—The moderate, continuous domestic demand for noncontaminating grinding materials for use in certain mineral-processing industries requiring a product with a minimum iron content has been met in recent years partly by one or two domestic producers and partly by imports.

In 1938 sales of domestic liners, which were less than in 1937, were reported only by the Jasper Stone Co., Sioux City, Iowa, the material marketed being quartzite quarried near Jasper, Rock County, Minn. Sales of quartzite pebbles by this company also were less than in 1937. A new producer, the King Solomon Mines Co., Black Bear (near Yreka), Siskiyou County, Calif., mined and used a considerable tonnage of ball-mill pebbles in its gold mill.

Flint grinding pebbles occur in the beaches derived from flint-bearing chalk cliffs on both the English and French coasts of the English Channel and on the islands off the coast of Denmark. France and Denmark are the only flint-pebble exporting countries, as the English production is insufficient for its own needs. Flint grinding pebbles are imported into the United States from both Denmark and France.

## NATURAL SILICATE ABRASIVES

*Pumice and pumicite.*—Sales of pumice and pumicite in 1938 were lower in quantity than in 1937 but were somewhat higher in value. Figure 2 shows the trend in sales of pumice and pumicite in recent years for various uses, and the following table gives the values of the total annual sales from 1934 to 1938.

*Pumice and pumicite sold or used by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 56,169 | $207,058 | 1937 | 71,007 | $301,936 |
| 1935 | 60,000 | 247,076 | 1938 | 65,742 | 312,886 |
| 1936 | 72,915 | 328,406 | | | |

Landes [6] has described the age, origin, distribution, and reserves of pumicite (volcanic ash) in the Great Plains, Cordilleran, and Pacific Coast regions of the United States and in the individual States. Volcanic ash is the finest material ejected from volcanoes. Larger, highly cellular, glassy ejecta are termed "pumice." Inasmuch as

[6] Landes, K. K., Distribution of Volcanic Ash; Bull. Am. Ceram. Soc., vol. 17, No. 8, August 1938, pp. 323–325.

Digitized by Google

volcanoes have been active in the West during many geologic periods, deposits of volcanic ash or its alteration products are found in the rocks of many ages. Most of the volcanic ash in the Cretaceous and older rocks has been altered to bentonite. Unchanged volcanic-ash deposits, however, occur in Tertiary, Pleistocene, and Recent strata. Most of the ash marketed today comes from Pleistocene deposits and the rest from Tertiary. The Pleistocene deposits of volcanic ash of the Great Plains occur in many distinct and separate deposits in protected dune areas. Most of the Tertiary ash, however, fell in

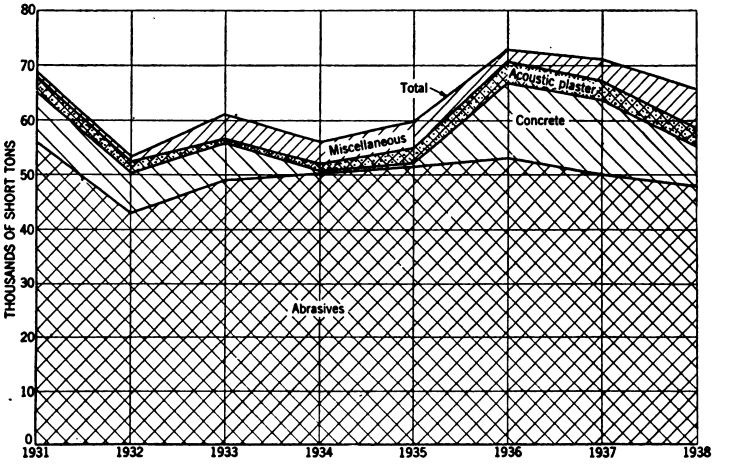

FIGURE 2.—Trend, by uses, of pumice and pumicite sold or used by producers in the United States, 1931–38.

large interior lakes, where it is interbedded with other sediments. The source volcanoes for the Pleistocene volcanic ash are thought to be members of the Capulin group in northeastern New Mexico. The Tertiary ash beds of the Great Plains area probably originated through volcanic activity in the Cordilleran area. The volcanic-ash deposits within the Cordilleran and Pacific Coast areas doubtless resulted from volcanism in those regions. Present exploitation is not making serious inroads on the immense reserves of these materials.

Pumicite (volcanic ash) was produced in 1938 in Kansas, Nebraska, and Oklahoma in the Great Plains area and in California and Oregon in the Pacific Coast region. Lump pumice was produced in the latter region only—in California and Oregon. A volcanic-tuff [7] deposit at Grants, N. Mex., was exploited in 1938 and the product ground and marketed as domestic pumice.

The quantities of pumice and pumicite sold or used in 1938 for all specified uses (except miscellaneous) declined from 1937. The greater part of the total is sold for abrasive purposes, such as cleansing and scouring compounds and hand soaps. The demand for this use has been relatively constant in recent years—roughly around 50,000 tons a year—and in 1938 the quantity sold or used was 47,013 tons. Sales for the next most important use, concrete admixture and concrete aggregate, after rising abruptly from a few hundred tons in 1935 to nearly 14,000 tons in 1936 and 1937, were curtailed to 7,596 tons in 1938. (See fig. 2.)

[1] 1937: Includes material used in asphalt, grading roads, chicken litter, filtering, rock gardens and landscaping, building tiles, floor sweep, and some unspecified uses; 1938: Includes material used in asphalt, filtering, rock gardens and landscaping, building tiles, and some unspecified uses.

The volcanic-ash deposits of Oklahoma were described in 1938 in a publication of the Oklahoma Geological Survey.[8] The manufacture of pumicite-concrete building blocks at Napa, Calif., by the Basalt Rock Co. was described in an article [9] published early in 1939.

In Iceland [10] crushed pumice stone mixed with cement is being employed for hollow building blocks for residential construction.

The use of volcanic ash as a ceramic raw material has not been extensive, although its practicability has been indicated both by laboratory and industrial applications. Plummer [11] described the effect of volcanic ash in glazes by comparing such glazes with those of nearly identical composition except that they contained feldspar or equivalent materials. The volcanic ash was used successfully in several types of glazes, replacing the feldspar and part of the flint and constituting in some glazes more than 50 percent of the total weight of the raw materials. No significant difference was noted between the volcanic-ash glazes and the control glazes except that the iron oxide colored the volcanic ash. Plummer considers that the use of volcanic ash to replace feldspar in glazes and glass batches offers a distinct economic advantage because of the low cost of this material and its finely divided natural condition, which should be of especial importance in colored glazes for roofing tile, wall tile, and low-priced pottery. The slight neutralization of the colors is said to give more pleasing effects in artware and ceramic sculpture.

*Garnet.*—The general decline in industrial activity in the United States in 1938 reacted on the sales of garnet, which in 1938 were only a little over half as large as in 1937. (See fig. 3.) Sales of abrasive garnet in 1938 were reported by four companies, but only three companies, one each in New York, New Hampshire, and North Carolina, mined garnet during 1938—the Barton Mines Corporation, North Creek, Warren County, N. Y.; Davenport Garnet Co., South Danbury, Merrimack County, N. H.; and the Celo Mines, Inc., Burnsville, Yancey County, N. C. The Warren County Garnet

Mills, Weaverton, Warren County, N. Y., sold garnet from stock. A little less than 2 tons of garnet were imported in 1938, the first imports of this material since 1933.

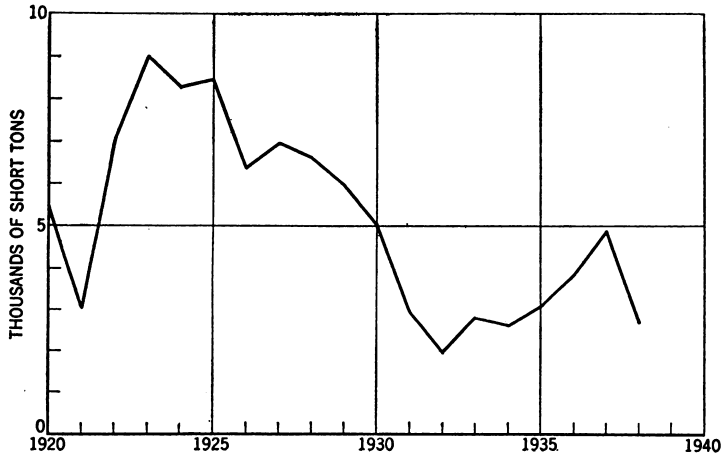

FIGURE 3.—Marketed production of abrasive garnet in the United States, 1920–38.

The following table shows the quantity and value of abrasive garnet sold or used by domestic producers since 1934.

*Abrasive garnet sold or used by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 2,591 | $214,815 | 1937 | 4,863 | $382,535 |
| 1935 | 3,060 | 256,520 | 1938 | 2,669 | 191,658 |
| 1936 | 3,820 | 315,913 | | | |

During 1938 domestic demand arose for a very fine grained abrasive of the type represented by the Belgian razor honestone ("coticule"), now imported into this country for use in sharpening razor blades and the microtome knives used in the preparation of microscope-slide specimens. The Belgian "coticule" is a regionally metamorphosed, argillaceous sedimentary rock occurring in the Ardennes in southeastern Belgium as thin, clear yellow to yellowish gray, compact, homogeneous, fine-grained beds ½ to 3 inches thick, interstratified with blue-gray or violet Cambrian phyllites, in some places merging gradually into them but more often sharply distinct in coloring.

Billions of tiny, nearly spherical, polyhedral, hard crystals of light-yellow manganese garnet, spessartite, in a soft sericite matrix, form the principal element of the "coticule" and explain its yellow color, hardness, peculiar fitness for hones, and manganese content (17 to 22 percent MnO). The average diameter of these microscopic garnets is about 0.0008 inch. Tiny rutile and tourmaline crystals also occur in the "coticule." The mineral composition of the phyllite differs from that of the "coticule" in that hematite and carbonaceous matter are present.

The beds of coticule and attached phyllite are cut in a characteristic manner. As the phyllite has abrasive qualities part of it is left

Digitized by Google

attached to the "coticule" to support it. The hones thus appear double-faced, with yellow "coticule" on one side and the softer blue-gray phyllite on the other.

Wright [12] presented the results of an extensive study to determine the varieties of garnets characteristic of different rock types. A remarkable constancy of association was shown between a given variety and a certain type of rock. His summary table of the major molecules of garnets in the rock types is reproduced here.

*Average proportion of major molecules of garnets in rock types*

| Rock type | Spessartite | Grossularite | Pyrope | Almandite | Andradite |
|---|---|---|---|---|---|
| Pegmatite | 47.1 | | | 41.8 | |
| Granite | 36.0 | | | 56.8 | |
| Garnets associated with contact action on siliceous rocks | 30.7 | | | 56.4 | |
| Biotite schists | | 6.0 | 13.8 | 73.0 | |
| Amphibole schists | | 20.7 | 20.3 | 53.6 | |
| Eclogites | | 18.5 | 37.4 | 39.1 | |
| Kimberlites and peridotites | | 9.0 | 72.3 | 13.4 | |
| Various basic rocks | | 28.7 | 20.7 | 34.4 | 15.6 |
| Calcareous contact rocks | | 51.5 | | | 40.8 |

The occurrence of garnets in Triassic conglomerate in York County, Pa., was described in 1938 by Stose and Glass.[13]

Miller [14] described the occurrence, character, and possible genesis of certain garnet deposits of the Adirondacks, including the Hooper, Barton, old Hooper, and Humphrey Mountain mines.

The occurrence of garnets in California was described by Sperisen [15] and Pabst.[16]

## NATURAL ALUMINA ABRASIVES

*Corundum.*—No corundum has been mined in the United States since 1918, and regular annual production stopped in 1906. Domestic demand for crude corundum in 1938 was met by the importation of 2,098 short tons valued at $138,629, chiefly from the Union of South Africa. Both the quantity and value of imports were slightly greater than in 1937. (See fig. 4.) Virtually all corundum and emery is imported in the crude state and crushed and graded in this country for the domestic market. Imports of both corundum ore and emery ore have been curtailed sharply in depression periods.

*Emery.*—No sales of domestic emery were made in 1938. Production in the United States in recent years has been confined to the deposit of spinel-bearing emery near Peekskill, Westchester County, N. Y. Competition of artificial abrasives and imported emery and corundum has caused a general downward trend in the demand for domestic emery since the World War. Since 1933 sales have been

only a few hundred tons a year, and in 1938 they failed entirely. Temporary revivals in domestic sales occurred in 1928 and 1933 following curtailments in imports of emery and corundum. (See fig. 4.)

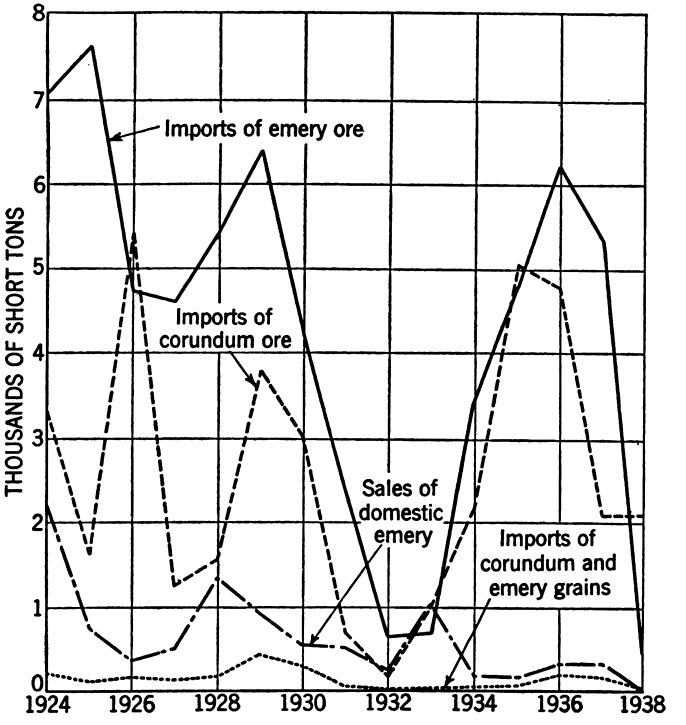

FIGURE 4.—Comparison of sales of domestic emery with imports of emery and corundum in the United States, 1924–38.

*Emery sold or used by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 189 | $1,800 | 1937 | 320 | $2,780 |
| 1935 | 176 | 1,606 | 1938 | | |
| 1936 | 325 | 2,900 | | | |

## NATURAL CARBON ABRASIVES

*Abrasive or industrial diamond.*—The demand for industrial or abrasive diamond in the United States is met entirely by imports of black diamonds (carbonados) and bort. Black diamonds come chiefly from the State of Bahia (Brazil). Bort cull stones from the gem-diamond industry originate principally in the Union of South Africa. In 1938 imports of abrasive diamond into the United States were valued at $4,295,704, a decrease of nearly $2,500,000 from 1937. Declines occurred in the quantity of both bort and "glaziers' and engravers', unset, and miners' diamonds" imported. Imports of bort dropped 73 percent and those of the other classification 26 percent.

Digitized by Google

Only slight declines occurred in the average values of the two types of industrial diamond, and these probably were due largely to lowered prices resulting from the lessened demand. Bort values fell from $17.38 per carat in 1937 to $16.67 in 1938; values of the other class dropped from $3.47 per carat in 1937 to $3.02 in 1938.

There were no known developments in 1938 in the domestic diamond-bearing district near Murfreesboro, Pike County, Ark.

## ARTIFICIAL ABRASIVES

The artificial-abrasive industry suffered a substantial set-back in 1938. Sales of silicon carbide, aluminum oxide, and metallic abrasives were less than in 1937, and those of the first two were even less than in 1936, reversing the upward trend in all three since 1933. The following table shows the sales of these three classes of abrasive materials for the 5-year period 1934–38.

*Crude artificial abrasives sold, shipped, or used, from manufacturing plants in the United States and Canada, 1934–38* [1]

| Year | Silicon carbide [2] | | Aluminum oxide [2] | | Metallic abrasives | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 18,038 | [3] $1,753,019 | 46,496 | [3] $3,665,226 | 10,312 | $554,452 | 74,846 | $5,972,697 |
| 1935 | 24,266 | [3] 2,164,728 | 49,990 | [3] 3,784,726 | 14,593 | 741,633 | 88,849 | 6,691,087 |
| 1936 | 29,342 | 2,139,919 | 69,825 | 3,913,155 | 24,667 | 1,221,912 | 123,834 | 7,274,986 |

[1] Bureau of Mines not at liberty to publish data for United States separately.
[2] Includes material used for refractories and other nonabrasive uses.
[3] Includes value of some grain.
[4] Production.

Production of silicon carbide centers in the Niagara Falls region in New York and that of aluminum oxide in the Niagara Falls region and at Anniston, Ala. Production of metallic abrasives is scattered through several Northern States from Michigan to New Hampshire. The following companies reported the manufacture of artificial abrasive materials in 1938.

SILICON CARBIDE:
The Carborundum Co., Niagara Falls, N. Y.
The Exolon Co., Blasdell, N. Y.
General Abrasive Co., Inc., College Avenue, Niagara Falls, N. Y.
Norton Co., 1 New Bond Street, Worcester, Mass.

ALUMINUM OXIDE:
Abrasive Co. of Canada, Ltd., Tacony and Fraley Streets, Bridesburg, Philadelphia, Pa. (or Arvida, Canada).
The Carborundum Co., Niagara Falls, N. Y.
The Exolon Co., Blasdell, N. Y.
General Abrasive Co., Inc., College Avenue, Niagara Falls, N. Y.
Monsanto Chemical Co., 1700 South Second Street, St. Louis, Mo.
Norton Co., 1 New Bond Street, Worcester, Mass.

METALLIC ABRASIVES:
Alloy Metal Abrasive Co., 311 West Huron Street, Ann Arbor, Mich.
The American Steel Abrasives Co., Galion, Ohio.
The Globe Steel Abrasive Co., Mansfield, Ohio.
The National Metal Abrasive Co., 3560 Norton Road, Cleveland, Ohio.
Pittsburgh Crushed Steel Co., Alleghany Valley Railroad and Sixty-first Street, Pittsburgh, Pa.
Steelblast Abrasives Co., Cleveland, Ohio.
Harrison Abrasive Corporation, Manchester, N. H.

Tone [17] discussed in considerable detail the composition, hardness, crystal structure, and refractoriness of synthetic abrasive materials. Late in 1938 the National Bureau of Standards [18] issued a circular describing the manufacture of abrasive grain and abrasive products, with a bibliography of recent literature on abrasives. The production of silicon carbide, aluminum oxide, and boron carbide is described. Silicon carbide (SiC) is made in a resistance-type electric furnace, usually operated at an energy rate of 1,500 kilowatts, with a charge of approximately 60 percent silica and 40 percent low-ash petroleum coke to which are added variable quantities of ordinary wood sawdust and sodium chloride. Artificial corundum or "fused alumina" ($Al_2O_3$) is produced from calcined bauxite in steel-lined, water-cooled furnaces of the arc type. Coke and iron borings are added to the charge to aid in the reduction and separation of the impurities. Boron carbide ($B_4C$) is made in a resistance-type furnace with coke and dehydrated boric acid.

Metallic abrasives include crushed steel, steel shot, and angular steel grit. Crushed steel is made [19] from high-carbon and crucible sheet steel specially treated to impart brittleness. It is then crushed to sizes ranging from 2- to 200-mesh. After screening, each batch is heat-treated and separated into 25 sizes ranging from 20- to 200-mesh. Sizes from 70-mesh upward are screened on silk bolting cloth, and the finer sizes in powder form are used in steel cement, various chemical compounds, and fireworks sparklers.

Steel shot is merely chilled cast iron. Only raw materials of the highest grade, including selected scrap and charcoal iron, are used in its manufacture; these are melted in a cupola. During the casting period the molten metal is separated into small spherical globules by directing high-pressure steam or heated compressed air against the stream of metal. The globules are blown into water and cooled. The shot, made brittle by the rapid cooling, is heat-treated to impart a temper of hardness and graded by mechanical means into 15 sizes that range from 4- to 90-mesh. Coarse material left on the 4-mesh screen is granulated by specially designed crushing equipment and in this form is known as angular steel grit. The crushed material is heat-treated to impart toughness and durability, then graded into 15 sizes ranging from 7- to 100-mesh. Steel shot and angular steel grit are used for many abrasive purposes.

## MISCELLANEOUS ABRASIVE MATERIALS

Besides the materials already discussed several others are used for abrasive purposes. Several oxides—tin oxide, rouge and crocus (forms of ferric oxide), chromium oxide, magnesium oxide, manganese oxide, and lime—as well as clay, talc, and whiting, are used as polishing agents. Silt, clay, feldspar, and other substances sometimes are used as abrasives.

## FOREIGN TRADE [20]

The decline of nearly 3 million dollars in the total value of abrasive materials imported for consumption in the United States in 1938 from

[17] Tone, F. J., The Quest for Hard Materials: Ind. and Eng. Chem. (Ind. Ed.), vol. 30, No. 2, February 1938, pp. 232-242.

[20] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

that of 1937 was due principally to the decrease of nearly half a million carats in imports of glaziers' and engravers' (unset) and miners' diamonds. Imports of these types of diamonds, which constitute the greater part of the total value of all imported abrasives, declined from 1,885,970 carats valued at $6,542,365 in 1937 to 1,396,247 carats valued at $4,213,412 in 1938. Declines were registered also in imports of most other types of abrasives, but imports of garnets, rough or unmanufactured millstones, hones, oilstones, and whetstones, and corundum ore increased. Garnets were imported for the first time in several years. The declines in imports of corundum (and emery) grains, diamond dust, bort, and emery ore were especially marked.

The total value of exports of all recorded classes of natural abrasives in 1938 was less than in 1937, the decline in the values of grindstones and abrasive wheels (emery and corundum) being much greater than the increase in the value of the much larger remaining class, which includes all other natural abrasives.

| Foreign trade | 1251 |
| World production | 1252 |

Demand for sulfur was lower in 1938 than in 1937, and world production declined because of a smaller output in the United States. Production in Italy, the second largest source, increased moderately. Data for Japan, normally the third largest producer, are not available. Exports from the principal sources of supply decreased, owing not only to lower rate of consumption but also to increased recovery in some market areas of elemental sulfur as a byproduct in industrial processes. Germany, formerly a large market for native sulfur, has now developed a supply of elemental sulfur from byproduct sources adequate for its own increasing needs. Spain, Japan, and Norway were the largest producers of pyrites in 1938, but operations in Spain, the largest source, were hampered by the civil war.

Consumption of both sulfur and pyrites in the United States decreased in 1938. Probably the most significant event of 1938 in the domestic industry was the reduction in the quotations on sulfur at the beginning of the last quarter—the first change in the quotations since 1926. Maintenance of the price at $18 per long ton throughout the good years as well as the depression has made the market attractive and has resulted in technical investigations into sulfur production, as well as research for substitutes and substitute processes which have been somewhat successful. Apparently pressure resulting from increased production of byproduct sulfur and additional domestic production of native sulfur affected the change in sulfur quotations. While domestic production dropped in 1938 shipments recorded an even greater decline, resulting in record stocks at the mines.

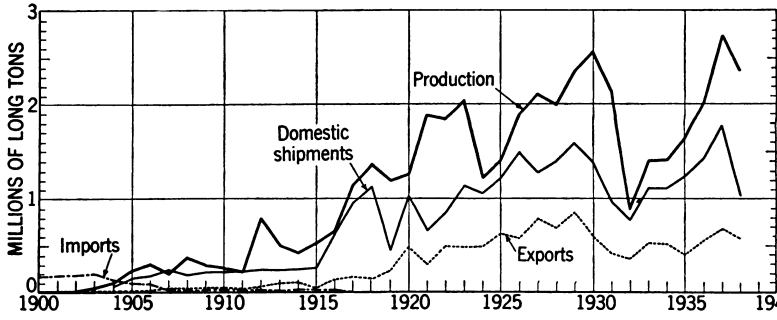

FIGURE 1.—Domestic production, domestic shipments, exports, and imports of crude sulfur, 1900–1938.

The production of native sulfur in the United States up to and including 1938 has totaled more than 43 million long tons. Virtually the entire output has been made since 1900. The principal trends in the sulfur and pyrites industries are shown in figures 1 and 2.

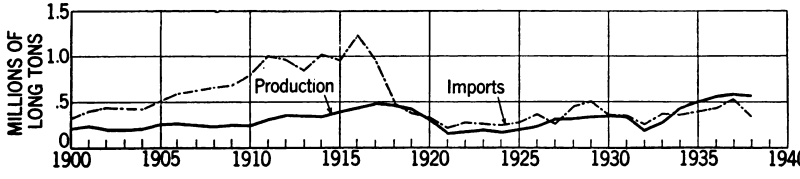

FIGURE 2.—Domestic production and imports of pyrites, 1900–1938.

## SULFUR

*Domestic production.*—Production of sulfur in the United States in 1938 decreased 13 percent from the record total in 1937. Curtailment of shipments from domestic mines, however, was more severe, comprising 34 percent of the record figure in 1937. Several hundred tons of sulfur-bearing ore used for agricultural purposes are not included in the total for 1937. None of this material was reported in 1938.

Digitized by Google

*Sulfur produced and shipped in the United States, 1934–38*

| Year | Produced (long tons) | Shipped | | Year | Produced (long tons) | Shipped | |
|---|---|---|---|---|---|---|---|
| | | Long tons | Approximate value | | | Long tons | Approximate value |
| 1934 | 1,421,473 | 1,613,838 | $28,900,000 | 1937 | 2,741,970 | 2,466,512 | $44,300,000 |
| 1935 | 1,632,590 | 1,634,990 | 29,300,000 | 1938 | 2,393,408 | 1,628,847 | 27,300,000 |
| 1936 | 2,016,338 | 1,968,820 | 35,400,000 | | | | |

Eighty-six percent of the domestic output of sulfur reported for 1938 came from Texas and the bulk of the remainder from Louisiana. California and Utah produced only 4,158 long tons. Thus, the first two States produced more than 99 percent of the domestic output. Active mines in 1938 are listed in the following table.

*Mines that produced sulfur in the United States in 1938*

| Operating company | Name of mine | Location of mine |
|---|---|---|
| California: | | |
| Nevada Pacific Sulphur Co | Gup No. 1 | Oasis, Inyo County. |
| Western Mining Corporation | Crater | Bigpine, Inyo County. |
| Louisiana: | | |
| Freeport Sulphur Co | Grande Ecaille | Port Sulphur, Plaquemines Parish. |
| Texas: | | |
| Duval Texas Sulphur Co | Boling Dome | Boling, Wharton County. |
| Do | Orchard Dome | Orchard, Fort Bend County. |
| Freeport Sulphur Co | Hoskins Mound | Freeport, Brazoria County. |
| Jefferson Lake Oil Co., Inc | Clemens Dome | Brazoria, Brazoria County. |
| Texas Gulf Sulphur Co | Boling Dome | Newgulf, Wharton County. |

*Byproduct sulfur.*—A small quantity of byproduct sulfur is produced annually incident to the purification of manufactured fuel gases. In 1938, 3,674 long tons were produced from this source, of which 2,507 tons were shipped; the rest is stored or accumulated in dumps at various plants. Several processes are used. The largest quantity is recovered by the Thylox process,[2] although a considerable quantity is recovered by the Ferrox process. The product is shipped either as 99 percent or more pure sulfur or as a sludge or paste containing 33 to 50 percent sulfur. The output is not included in the sulfur-production figures of the United States.

The conversion of waste material, which may be somewhat of a nuisance, into a marketable product is the object of a study conducted by the Bureau of Mines, designed to recover sulfur from smelter smoke.[3]

*Stocks.*—As production exceeded shipments in 1938, stocks at the mines increased during the year and on December 31 amounted to 4,200,000 long tons.

*Price.*—The price of sulfur was reduced in 1938—the first change in the quotations since 1926. The price at the mines dropped from

[2] Foxwell, G. E., and Grounds, A., Thylox Process for the Recovery of Sulfur from Gases Containing Hydrogen Sulfide: Chem. and Ind., vol. 58, No. 8, Feb. 25, 1939, pp. 163–170.

[3] Roberson, A. H., and Marks, G. W., Fixation of Sulfur from Smelter Smoke: Progress Reports—Metallurgical Division, No. 26: Bureau of Mines Rept. of Investigations 3415, 1938, pp. 1–45.

Digitized by Google

$18 to $16 per long ton at the beginning of the last quarter, while the ex-vessel quotation along the Atlantic seaboard was reduced from $22 to $20.50 at all ports except Boston, Mass., and Portland, Maine. where the price was $22.50.

*Byproduct sulfuric acid.*—Treatment of copper and zinc ores yields large quantities of sulfur, which is recovered at the mills as a pyrites concentrate or at the smelters as sulfuric acid. Production of pyrites concentrate is discussed in the pyrites section of this report. In smelting copper and zinc concentrates the sulfur is driven off as sulfur dioxide gas, which is used at many smelters in the manufacture of sulfuric acid. The equivalent of about 155,000 long tons of sulfur was recovered as sulfuric acid annually from this source during the 3 years ended in 1937. Such sulfur is not included in the sulfur production figures for the United States, but the following table shows the output of byproduct acid at both copper- and zinc-smelting plants. The acid reported is only that made from the sulfur content of sulfide ores. The figures for 1934 to 1937, inclusive, do not include the acid made from the pyrites concentrate in Tennessee but do include the relatively small amount of acid made from pyrites concentrate in Wisconsin. For 1933 pyrites acid from both States is included.

*Byproduct sulfuric acid (expressed as 60° B.) produced at copper and zinc plants in the United States, 1933–37, in short tons* [1]

| | 1933 | 1934 | 1935 | 1936 | 1937 |
|---|---|---|---|---|---|
| Copper plants | [2] 301,075 | 168,676 | 160,151 | 226,738 | [2] 291,638 |
| Zinc plants | 355,027 | 406,984 | 443,476 | 505,882 | 542,356 |
| | [2] 656,102 | 575,660 | 603,627 | 732,620 | [3] 833,994 |

[1] Figures for 1938 not yet available.
[2] Includes acid made from pyrites concentrates in Tennessee.
[3] Includes a small amount of sulfuric acid produced as a byproduct in the roasting of high-sulfide gold and silver concentrates.

Processes recently have been developed for the recovery of sulfuric acid in the treatment of natural gases and refinery gases to remove hydrogen sulfide, and plants utilizing these processes are now operating. Acid from this source is not included in the byproduct acid figures in the preceding table.

*Consumption.*—The apparent domestic consumption of sulfur in 1938 dropped 41 percent below the record level in 1937.

*Apparent consumption of sulfur in the United States, 1934–38, in long tons*

| | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Shipments | 1,613,838 | 1,634,990 | 1,968,820 | 2,466,512 | 1,628,847 |
| Imports | 5,839 | 1,763 | 530 | 398 | 51 |
| | 1,619,677 | 1,636,753 | 1,969,350 | 2,466,910 | 1,628,898 |
| Exports: | | | | | |
| Crude | 507,115 | 402,383 | 547,199 | 675,297 | 575,957 |

The consumption of sulfur in various industries from 1934 through 1938 has been estimated by Chemical and Metallurgical Engineering as follows:

*Sulfur consumed in the United States, 1934–38, by uses, in long tons* [1]

| Use | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Chemicals | 512,000 | 555,000 | 620,000 | 777,000 | 484,000 |
| Fertilizer and insecticides | 247,000 | 239,000 | 266,000 | 415,000 | 220,000 |
| Pulp and paper | 176,000 | 204,000 | 260,000 | 302,000 | 174,000 |
| Explosives | 43,000 | 42,000 | 53,000 | 68,000 | 50,000 |
| Dyes and coal-tar products | 34,000 | 39,000 | 46,000 | 49,000 | 40,000 |
| Rubber | 30,000 | 33,000 | 39,000 | 37,000 | 29,000 |
| Paint and varnish | 4,000 | 48,000 | 54,000 | 64,000 | 50,000 |
| Food products | 4,000 | 4,000 | 4,500 | 6,000 | 5,500 |
| Miscellaneous | 60,000 | 68,500 | 78,000 | 82,000 | 47,500 |
| | 1,110,000 | 1,232,500 | 1,420,500 | 1,800,000 | 1,100,000 |

[1] Figures for 1937 and 1938 are not truly representative of consumption but rather of shipments to these specified industries. In 1938 consumers carried over large stocks from 1937, so that actual consumption in 1937 was less than the figures indicate and consumption in 1938 was larger than the above total.

Production of sulfuric acid, the chief use of sulfur in the United States, declined in 1938, reflecting the decreased consumption of chemicals. Consumption of acid in the domestic fertilizer industry, the largest outlet, dropped owing to the reduction in production of superphosphate. The T. V. A. continued its researches into the manufacture of phosphate fertilizers and announced successful operation of a small commercial-sized unit for the manufacture of calcium metaphosphate, a highly concentrated material containing 28 percent phosphorus, which uses phosphorus produced by electric furnaces.[4] Activities in the petroleum-refining industry, the second largest consumer of sulfuric acid, held up rather well, resulting in a relatively small decline in acid consumption. This industry, however, is also a potential source of acid, and several plants are producing acid as a byproduct in the treatment of refinery and natural gases.

The consumption of sulfuric acid, by industries, from 1934 through 1938 has been estimated by Chemical and Metallurgical Engineering as follows:

*Sulfuric acid (expressed as 50° B.) consumed in the United States, 1934–38, by industries, in short tons*

| Industry | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Fertilizer | 1,650,000 | 1,720,000 | 1,987,000 | 2,510,000 | 2,100,000 |
| Petroleum refining | 1,100,000 | 980,000 | 1,100,000 | 1,210,000 | 1,120,000 |
| Chemicals | 910,000 | 940,000 | 955,000 | 1,020,000 | 790,000 |
| Coal products | 500,000 | 625,000 | 770,000 | 860,000 | 585,000 |
| Iron and steel | 475,000 | 630,000 | 770,000 | 850,000 | 500,000 |
| Other metallurgical | 400,000 | 520,000 | 560,000 | 620,000 | 350,000 |
| Paints and pigments | 330,000 | 400,000 | 450,000 | 525,000 | 430,000 |
| Explosives | 180,000 | 175,000 | 222,000 | 230,000 | 185,000 |

The leading domestic producers have carried on research work with a view to broadening the market for sulfur, but to date no large-tonnage outlet has been developed. New applications for sulfur have been discussed by Duecker.[5]

*Foreign trade.*—Exports of sulfur in 1938 dropped 15 percent from the 1937 figure but were larger than in any other year since 1930; data by years from 1934 to 1938, inclusive, follow.

*Sulfur imported into and exported from the United States, 1934–38*

| Year | Imports | | Exports | | | |
|---|---|---|---|---|---|---|
| | Ore | | Crude | | Crushed, ground, refined, sublimed, and flowers of | |
| | Long tons | Value | Long tons | Value | Long tons | Value |
| 1934 | 5,839 | $76,631 | 507,115 | $9,364,501 | 10,112 | $398,043 |
| 1935 | 1,763 | 26,164 | 402,383 | 7,582,293 | 10,916 | 418,532 |
| 1936 | 530 | 10,141 | 547,199 | 10,147,038 | 19,708 | 746,985 |
| 1937 | 398 | 4,724 | 675,297 | 12,155,253 | 13,533 | 509,133 |
| 1938 | 51 | 562 | 575,957 | 10,332,529 | 12,707 | 469,773 |

Shipments of crude sulfur to Canada, formerly the largest market, fell abruptly in 1938 and amounted to only 43 percent of the 1937 figure. Australia increased its takings 52 percent over 1937 and became the largest customer. Canada, however, continued as the largest market for treated sulfur. The following table shows the distribution of exports by countries of destination for 1937 and 1938.

*Sulfur exported from the United States, 1937–38, by countries*

| Country | Crude | | | | Crushed, ground, refined, sublimed, and flowers of | | | |

## THE INDUSTRY IN 1938, BY STATES

*California.*—Two operators in California reported production in 1938, but by far the larger output came from the Crater Group mine, Inyo County operated by the Western Mining Corporation.

*Louisiana.*—Production of sulfur in Louisiana in 1938 totaled 328,405 long tons and was made by the Freeport Sulphur Co. from its operations at Grand Ecaille, Plaquemines Parish, where further plant improvements were under way during the year.

An amendment to the Louisiana Constitution adopted November 8, 1938, provided that the State Severance Tax shall not exceed $1.03 per long ton, effective as of July 27, 1938. The previous tax was $2 per ton. The amendment also provides for an ad-valorem tax on unmined sulfur previously exempt.

*Texas.*—Texas supplied 86 percent of the domestic output in 1938. Six operations contributed to the total, but the largest output came from the Boling Dome property of the Texas Gulf Sulphur Co. The following table, compiled from information issued by the Texas State Comptroller's Office, shows the quarterly production of sulfur in Texas for 1938.

*Sulfur produced in Texas in 1938, by companies, in long tons*

| Company | First quarter | Second quarter | Third quarter | Fourth quarter | Total |
|---|---|---|---|---|---|
| Texas Gulf Sulphur Co | 399,626 | 318,210 | 268,882 | 235,902 | 1,222,620 |
| Freeport Sulphur Co | 91,160 | 91,095 | 88,915 | 84,615 | 355,785 |
| Jefferson Lake Oil Co., Inc | 58,825 | 56,803 | 52,319 | 100,182 | 268,129 |
| Duval Texas Sulphur Co | 35,461 | 56,000 | 62,870 | 58,075 | 212,406 |
| | 585,072 | 522,108 | 472,986 | 478,774 | 2,058,940 |

Digitized by Google

The Texas Gulf Sulphur Co. also produced at Long Point Dome where operations were suspended during 1938 owing to exhaustion of sulfur on the tract then operated. The Freeport Sulphur Co., the second largest producer, continued operations at Hoskins Mound. Output at Clemens Dome, Brazoria County, which was begun in 1937 by the Jefferson Lake Oil Co., Inc., increased substantially in 1938 when additional capacity was installed. In addition to its output on certain tracts on Boling Dome, the Duval Texas Sulphur Co. inaugurated production at Orchard Dome, Fort Bend County, in 1938.

*Utah.*—Sulfur production in Utah in 1938 came from the Utah Sulphur Industries plant at Beaver, Beaver County.

## WORLD PRODUCTION

World production of sulfur in 1938, including elemental sulfur recovered in the treatment of pyrites and as a byproduct from the manufacture of gas and gasoline in Germany, is estimated at 3,200,000 long tons. The following table shows the output of native sulfur for the world from 1934 through 1938.

*World production of native sulfur, 1934–38, in long tons* [1]

[1] Sulfur is also believed to be produced in the U. S. S. R., but the amount of its production is unknown.
[2] Data not available.
[3] In addition, the following quantities of sulfur rock are reported: 1935, 4,785 tons (77.5 percent sulfur); 1936, 11,612 tons (40–80 percent sulfur); and 1937, 1,050 tons.
[4] Less than 1 ton.
[5] In addition, the following quantities of sulfur rock are reported: 1934, 21,820 tons; 1935, 18,738 tons; 1936, 20,743 tons; and 1937, 19,793 tons.
[6] In addition, the following quantities of sulfur rock are reported: 1934, 4,706 tons; 1935, 20,764 tons; and 1936, 31,576 tons. Similar data are not available for 1937–38.
[7] Crude sulfur product.
[8] Refined sulfur, exclusive of that made from imported crude sulfur.

*Canada.*—Elemental sulfur is being produced in the treatment of base-metal smelter gas at Trail, British Columbia, by the Consolidated Mining & Smelting Co. The first commercial unit went into production in 1936,[6] and 12,083 long tons were produced in 1937. Data on output in 1938 are not available, but a 50-ton-per-day unit was added to the plant capacity. The Aldermac Mines, Ltd., is planning to recover sulfur by the Comstock-Westcott process from the cupriferous

[6] Kirkpatrick, S. D., Trail Solves Its Sulfur Problem: Chem. and Met. Eng., vol. 45, No. 9, September 1938, pp. 483–485.

Digitized by Google

pyrite output of the Aldermac mine near Rouyn, Beauchastel Township, Quebec. Imports of sulfur into Canada dropped sharply in 1938, amounting to only 83,658 long tons compared with 201,504 tons in 1937.

*Chile.*—The Chilean Government is interested in promoting the production of sulfur both directly and through such semiofficial institutions as the Miners Credit Bank. Data on production for 1938 are not yet available, but the total may reach 20,000 long tons. Exports, however, were much lower than in 1937, amounting to only 3,794 tons for the first 11 months compared with 19,378 tons for the same period in 1937.

*Germany.*—Germany produces no native sulfur, and in the past its requirements have been met by imports, largely from the United States; imports in 1938 were 101,958 long tons, of which 65 percent came from Italy. Much of the sulfur imported into Germany is transshipped to nearby countries; exports in 1938 were 22,876 tons. In recent years the production of byproduct sulfur has been making rapid progress, and by 1940 Germany may be self-sufficient. It is believed that output of elemental sulfur in 1938 from all sources, notably from coking plants, low-temperature carbonization plants, and gasoline hydrogenation plants, may have reached 70,000 tons or nearly two-thirds of requirements. Formerly nearly the entire German output of elemental sulfur came from desulfurization at coke plants, but most of the gain in production recently has been the result of installation of improved recovery methods at gasoline hydrogenation plants, now the main source of supply.

*Iceland.*—A plant for the production of sulfur at Myvatan was under construction late in 1938. Plans call for an output of 4,000 long tons a year from deposits in northern Iceland.

*Italy.*—Italy, including Sicily, is the world's second-largest producer of sulfur. Production in 1938 was 370,913 long tons compared with 338,101 tons in 1937. Exports of crude and refined sulfur from Italy dropped sharply from 384,067 tons in 1937 to 223,804 tons in 1938.

*Japan.*—Data on the production of sulfur in Japan in 1938 are not available; exports were 31,012 long tons compared with 54,961 tons in 1937.

*Norway.*—Production of sulfur in Norway results from the treatment of cupriferous pyrites at the Thamshavn plant of the Orkla Metal Co. Output was at a lower level in 1938 than in 1937. Exports in 1938 were 75,420 long tons compared with 95,695 tons in 1937. Although Norway has been an exporter of sulfur since 1932, it continues to import sulfur; imports in 1938 were 6,553 tons.

*Portugal.*—Production of elemental sulfur from pyrites at the San Domingos mine in the Province of Alemtejo was begun in 1935. Output in 1938 was 11,059 long tons compared with 13,021 tons in 1937; imports in 1938 were 3,408 tons compared with 2,336 tons in 1937.

*Spain.*—The output of native sulfur in Spain is augmented by elemental sulfur obtained in the treatment of pyrites. Figures for recent years are not available.

*Sweden.*—Elemental sulfur recovered as a byproduct of smelter gases by the Boliden Co.[7] at Ronskar in North Sweden is the only sulfur produced in Sweden. Output at this plant was 17,512 long

[7] Palen, A. G. Paul, Boliden Improves Work at Ronskar Smelter: Eng. and Min. Jour., vol. 139, No. 9, September 1938, pp. 54–55.

Digitized by Google

tons in 1938 compared with 18,141 tons in 1937. Imports of sulfur in 1938 were 47,309 tons compared with 83,009 tons in 1937.

## PYRITES

*Domestic production.*—Production of pyrites (ores and concentrates) in the United States in 1938 dropped 5 percent from the record figures in 1937 but was greater than in any other year. Of the 1938 total, 101,701 long tons were lump, and the rest was fines; most of the fines were flotation concentrates.

*Pyrites (ores and concentrates) produced in the United States, 1934–38*

| Year | Quantity | | Value | Year | Quantity | | Value |
|---|---|---|---|---|---|---|---|
| | Gross weight (long tons) | Sulfur content (percent) | | | Gross weight (long tons) | Sulfur content (percent) | |
| 1934 | 432,524 | 38.8 | $1,216,363 | 1937 | 584,166 | 39.7 | $1,777,787 |
| 1935 | 514,192 | 39.5 | 1,583,074 | 1938 | 555,629 | 39.4 | 1,685,766 |
| 1936 | 547,236 | 39.6 | 1,666,194 | | | | |

The quantity of pyrites (ores and concentrates) sold or consumed by producing companies totaled 524,120 long tons in 1938 compared with 568,470 tons in 1937. In 1938, 163,711 tons were sold by producers compared with 181,322 tons in 1937. All sales in both years were to domestic consumers. Prices quoted by trade journals are for imported pyrites and are given in cents per long-ton unit, c. i. f. Atlantic ports; quotations, which are nominal, were unchanged at 12–13 cents per long-ton unit throughout the year.

Tennessee was the principal producing State in 1938; other States producing were California, Colorado, Illinois, Kansas, Missouri, Montana, New York, Virginia, and Wisconsin.

### THE INDUSTRY IN 1938, BY STATES

*California.*—The Mountain Copper Co. was the only producer of pyrites in California in 1938; output came from the Hornet mine in Shasta County.

*Colorado.*—One operator shipped pyrites concentrates in Colorado in 1938. No pyrites was shipped from the mill-tailings dump of the Colorado zinc-lead mill in Lake County during the year.

*Illinois.*—In 1938 two coal operators in Illinois, the Peabody Coal Co. in Christian County and the Midland Electric Coal Corporation in Henry County, produced and shipped pyrites (coal brasses) recovered as a byproduct in coal-cleaning operations. The pyrites was used in the manufacture of sulfuric acid.

*Kansas.*—The Mineral Products Co. produced 17,757 long tons of pyrites (coal brasses) in 1938 at West Mineral, Cherokee County. Shipments, which averaged 47 percent sulfur, were consigned to St. Louis, Mo., where they were used in acid making.

*Missouri.*—Two operators produced and shipped 28,828 long tons of pyrites—the total output of Missouri in 1938. Shipments averaged

Digitized by Google

48.8 percent sulfur and moved to acid plants in the St. Louis area. The largest producer was the Moselle No. 10 mine in Phelps County, operated by Thomas and Williams. Other production came from the Judith Spring mine in Franklin County, operated by Julian Pickles.

*Montana.*—The pyrites produced in Montana in 1938 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in copper-plant operation.

*New York.*—During 1938 the St. Joseph Lead Co. produced 63,772 long tons of pyrites concentrate at its Balmat Mill in St. Lawrence County. The pyrites, which ran 49.72 percent sulfur, was produced as a flotation concentrate in the treatment of ore in which zinc is the principal value.

*Tennessee.*—The pyrites produced in Tennessee in 1938 came from the operations of the Tennessee Copper Co. in the Ducktown Basin, Polk County. It is produced as a flotation concentrate but does not enter the market, as the entire output is used by the company in the manufacture of sulfuric acid.

*Virginia.*—The only pyrites mined in Virginia in 1938 came from the Gossan mine at Cliffview, Carroll County, operated by the General Chemical Co., where a new mill was put into operation late in the year. The ore is mined by underground methods, and before the new mill was in operation lump ore was shipped. The entire output is used for the manufacture of sulfuric acid in the company plant at Pulaski.

*Wisconsin.*—The only company reporting pyrites production in Wisconsin in 1938 was the Vinegar Hill Zinc Co. in Grant County, which makes a pyrites concentrate in its magnetic separation plant at Cuba City from ore from several mines in the Platteville district.

## FOREIGN TRADE

Imports of pyrites in 1938 fell off 36 percent from the 1937 figure. Despite the civil war, Spain continued to supply the bulk of our imports; much smaller amounts came from Canada and Mexico. No pyrites has been exported since 1931.

*Pyrites, containing more than 25 percent sulfur, imported into the United States, 1934–38, by countries*

| Country | 1934 | | 1935 | | 1936 | | 1937 | | 1938 | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Long tons | Value | Long tons | Value | Long tons | Value | Long tons | Value | Long tons | Value |
| Belgium | | | | | 5,290 | $29,756 | | | | |
| Canada | 19,341 | $83,086 | 9,888 | $45,965 | 55,105 | 200,184 | 20,558 | $74,946 | 30,064 | $135,659 |
| Mexico | | | 85 | 430 | | | 549 | 1,473 | 202 | 522 |
| Portugal | | | | | 59,804 | 286,974 | 21,725 | 109,395 | | |
| Spain | 346,974 | 1,162,574 | 387,140 | 1,266,606 | 309,114 | 913,820 | 481,598 | 1,158,671 | 303,968 | 709,983 |
| | 366,315 | 1,245,660 | 397,113 | 1,313,001 | 429,313 | 1,430,734 | 524,430 | 1,344,485 | 334,234 | 846,164 |

The bulk of the imports of pyrites moves into Philadelphia and Maryland, where it is used in the manufacture of sulfuric acid.

## WORLD PRODUCTION

The following table shows world production of pyrites and its sulfur content. Most of the figures are taken from official sources of the countries concerned, supplemented by information from publications of the Imperial Institute and other reliable sources.

*World production of pyrites (including cupreous pyrites), 1936–38, in metric tons*

| Uruguay | | | | | 70 | (2) |
| Yugoslavia | 79,754 | 35,889 | 133,985 | 60,253 | 150,402 | 67,681 |

[1] In addition to countries listed Belgium, China, Spain, and the U. S. S. R. produce pyrites, but production data are not available.
[2] Data not available.
[3] Exports.

*Canada.*—Of the Canadian pyrites output in 1938, 30,099 metric tons containing 15,041 tons of sulfur came from Quebec and 10,365 tons containing 5,259 tons of sulfur from British Columbia. Most of the shipments from Quebec came from the Eustis mine of the Consolidated Copper & Sulphur Co. near Sherbrooke. The Aldermac Copper Corporation, operator of the Aldermac mine in Beauchastel Township,

Digitized by Google

made some shipments, but the bulk of its output of pyrites concentrates was stored awaiting the construction of a plant to manufacture elemental sulfur from pyrite. The output of British Columbia came from the Britannia mill, where pyrites concentrate is produced in the treatment of ores for the extraction of copper.

In addition, sulfuric acid is made from smelter gases at the Trail and Copper Cliff smelters, and elemental sulfur is made at Trail. In 1938, 81,663 metric tons of sulfur were recovered as sulfur or as sulfuric acid manufactured from smelter gases.

*Japan.*—Japan is one of the large producers of pyrites, but data on production in 1937 and 1938 are not available, owing to a ban on information pertaining to domestic production and consumption of pyrites. The entire output is consumed locally in the manufacture of sulfuric acid, and Japan is said to be self-sufficient as regards pyrites.

*Norway.*—Production of pyrites is the principal mining industry in Norway, and output exceeded 1,000,000 metric tons in 1938 for the third successive year. Exports were slightly lower in 1938, amounting to 654,955 tons compared with 676,535 tons in 1937. Some of the Norwegian pyrites is used locally for the production of elemental sulfur.

*Portugal.*—Production in Portugal was high in 1937 and 1938. Exports were 456,786 metric tons in 1938 compared with 652,750 tons in 1937.

*Spain.*—Spain is the principal world producer of pyrites, but war conditions undoubtedly affected operations during 1938. Data for recent years are not available.

# PHOSPHATE ROCK

By Bertrand L. Johnson and K. G. Warner

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1255 | Review by States | 1260 |
| Salient statistics | 1256 | Foreign trade | 1265 |
| Production | 1257 | World production | 1268 |
| Sales | 1257 | International trade | 1269 |
| Distribution of sales | 1258 | Technology | 1269 |
| Consumption | 1258 | Superphosphates | 1271 |
| Prices | 1259 | Basic slag | 1272 |
| Reserves | 1259 | | |

Export and domestic demand for American phosphate rock appears to have become stabilized. For the third time in three decades

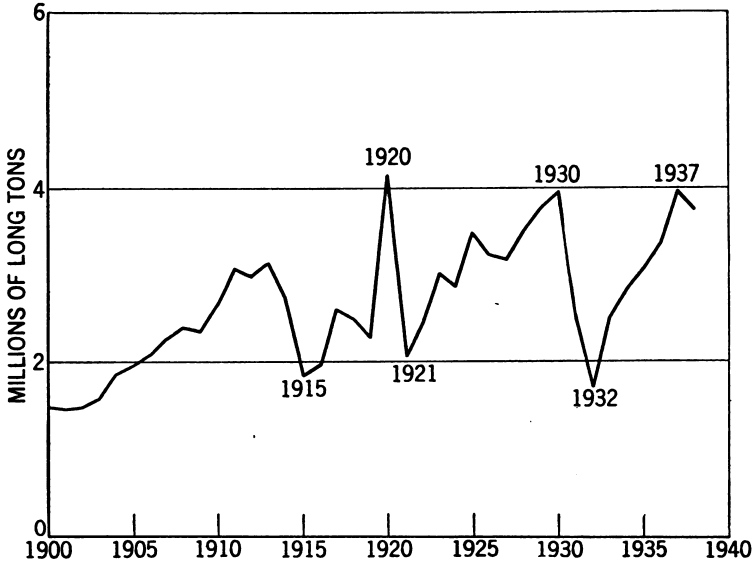

Figure 1.—Marketed production of United States phosphate rock, 1900–1938.

shipments from domestic mines fell from the 4-million-ton level into the broad horizontal trending zone within which they have fluctuated since the World War. (See fig. 1.) In 1938 exports were slightly greater than in 1937, but mine production, shipments, imports, and apparent consumption were all less than in 1937. Notwithstanding immense reserves, excess productive capacity, and adequate labor supply, general economic conditions have restricted domestic demand, and competition from superabundant foreign supplies has impeded further growth of export trade.

[7] Includes brown-rock matrix of sinter grade and sintered brown rock.

On May 20, 1938, the President of the United States in a special message to Congress called attention to the heavy drain on the supposedly limited phosphate reserves of Tennessee and Florida, and recommended the appointment of a joint congressional committee to study the "entire subject of phosphate resources, their use and service to American agriculture." Senate Joint Resolution 298, approved June 16, 1938, authorized an investigation by such a joint committee of the House and Senate, headed by Senator Pope, of Idaho, and hearings were held at Washington, D. C.; Pocatello, Idaho; Knoxville, Tenn.; and Lakeland, Fla. A report [1] of this committee was presented to Congress in January 1939. On July 2, 1938, pending the results of the congressional investigation, Secretary of the Interior Harold L. Ickes ordered suspension of the granting of phosphate-mining leases on the public domain.

Phosphate rock, although essential to our national defense and necessary to the production of foodstuffs in war or peace, is not classed as either a strategic or critical mineral. Reserves in the United States are large, and production is potentially much greater than any anticipated need. The main producing area (Florida), however, lies within a few miles of the Atlantic coast, and many of the country's super-

[1] Joint Congressional Committee to Investigate the Adequacy and Use of the Phosphate Resources of the United States, 76th Cong., 1st sess., Report on the Phosphate Resources of the United States: S. Doc. 21, Washington, D. C., 1939, 11 pp.

Digitized by Google

phosphate plants are in Atlantic coast cities, within easy reach of attack by sea.

The situation of the leading world powers with respect to phosphate rock is covered by McGrath and Jones [2] and Emeny.[3]

Several general papers on the phosphate-rock industry appeared during 1938.[4]

*Production.*—Mine production of phosphate rock in the United States was about 400,000 tons less in 1938 than in 1937. Output decreased markedly in Florida and slightly in the Western States but increased in Tennessee. Virginia again yielded apatite in nelsonite ores. Phosphate mining in South Carolina was resumed in 1938 on a small scale in the Coosaw River region.

*Phosphate rock mined in the United States, 1929–38, by States, in long tons*

| Year | Florida | Tennessee | Western States | United States | Year | Florida | Tennessee | Western States | United States |

[1] Includes small quantity of apatite from Virginia.
[2] Includes small quantity of apatite from Virginia and phosphate rock from South Carolina.

*Sales.*—The quantity of domestic phosphate rock sold or used by producers in 1938 was 5 percent less than in 1937. However, it exceeded that in any other years except 1920, 1929, and 1930. (See fig. 1.) The total value of shipments in 1938 was less than 1 percent below 1937.

*Phosphate rock sold or used by producers in the United States, 1934–38*

*Distribution of sales.*—Sales of low-grade rock (below 60 percent B. P. L.) have increased steadily from 4 percent of the total sales in 1933 to 12 percent in 1938 (450,858 long tons). This trend results from the development of electrothermic smelting of low-grade phosphatic material, the re-treatment of land-pebble wastes by flotation, and the utilization of the low-grade, hard-rock, waste-pond phosphates. Most sales of phosphate rock however, remain of grades above 68 percent B. P. L.

The following table, showing distribution of sales by classes of consumers, is compiled from reports of domestic producers of phosphate rock.

Superphosphate manufacture is by far the largest outlet for domestically produced phosphate rock, although the manufacture of nonfertilizer phosphate chemicals has increased greatly.

[1] Bone phosphate of lime.
[2] Figures not available.
[3] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[4] Includes grades of B. P. L. content between 68 and 70; 71; between 73 and 74; 78/76; 78; and above 85 percent; also dust, B. P. L. content not known.
[5] Includes exports, some calcined phosphate, and phosphatic material used in pig-iron blast furnaces, in the manufacture of concentrated fertilizers, as filler in asphalt mixtures, and as foundry facings.
[6] As reported to the Bureau of Mines by producers (exclusive of exports by dealers, etc.).

*Consumption.*—The apparent domestic consumption of phosphate rock in 1938 (2,605,403 tons) was about 300,000 tons less than that in 1937. A diagram on page 1171 of Minerals Yearbook 1938 shows the calculated extension of the logistic curve fitted to the domestic consumption of phosphate rock. The actual figures for 1938 tend to confirm the decreasing rate of increase and sidewise trend in domestic consumption forecasted by the logistic curve.

Digitized by Google

*Prices.*—Domestic quotations in the trade journals for the various grades of phosphate rock were unchanged throughout 1938, but in January 1939 a slight increase was reported in the price of the 68-percent B. P. L. grade of land pebble ($1.85 to $1.90) and larger decreases were reported in the prices for the higher grades. The 70-percent B. P. L. grade decreased from $2.35 to $2.15, the 72-percent grade from $2.85 to $2.40, and the 75-percent grade from $3.85 to $2.90. Such quotations, however, have been purely nominal in recent years, most actual sales having been made under contract.

*Reserves.*—Improved methods are making it possible to mine hitherto inaccessible deposits of phosphate rock and to utilize lower-grade deposits and waste dumps that could not have been worked profitably under old conditions. Previous estimates of reserves on higher-grade rock [5] were inadequate, and new estimates were needed. The new estimates, prepared in 1938 by the phosphate-mining industry, have been tabulated and discussed by Waggaman,[6] consulting engineer for the Phosphate Rock Institute, and his table comparing the old with the new estimates of reserves follows.

*Old and new estimates of phosphate reserves in selected States, by kind of rock*

[Thousands of long tons]

| State and kind of phosphate rock | Old estimates [1] | | New estimates [2] | |

The old estimate was based on phosphate rock averaging approximately 70 percent B. P. L., because only rock of this grade or better was considered suitable for the manufacture of superphosphate. The new estimate is based on material containing as low as 45 percent B. P. L. or capable of being beneficiated to this concentration and used in electric furnaces to produce elemental phosphorus. This estimate also includes as possible reserves huge quantities of phosphatic limestone in Tennessee and the phosphatic bedrock (Hawthorne formation) of the Florida land-pebble field. At present neither is used as a source of phosphorus, but small quantities of the former are used as chicken grit. Even if these low-grade formations are excluded, however, the new estimate is three to four times as large as the previous estimate in terms of phosphate rock and three times as large in terms of elemental phosphorus. If they are included, the present estimate is over seven times the older tonnage figures and is five times as large in terms of elemental phosphorus. The new estimates indicate a supply sufficient at the present rate of consumption for over 10,000 years and in Florida alone for 4,000 years.

Maynard [7] has discussed the preparation of these new reserve figures.

## REVIEW BY STATES

### FLORIDA

Although phosphate-rock production in Florida in 1938 was considerably less than in 1937, this State easily retained its leading position, producing three times as much as its nearest competitor, Tennessee. Both the quantity and value of the land-pebble and soft-rock shipments decreased, but shipments and value of hard rock increased. Producers of land pebble and hard rock in 1938 were the same as in the 2 previous years. (See Minerals Yearbook 1937, pp. 1318 and 1319.) Sintered phosphate matrix was made by the Pembroke Chemical Co., Pembroke, Fla., and shipped to Europe for further processing. Production of elemental phosphorus in Florida was begun in January 1938 at the only electric-furnace plant for that purpose in Florida—that of the Phosphate Mining Co. at Nichols, Fla.

Seven large companies operated in the land-pebble field. Three of these (International Agricultural Corporation, American Agricultural Chemical Co., and Amalgamated Phosphate Co.) contributed 61 percent of the total shipments in 1938. In the hard-rock field only three companies operated. The limited output of soft rock was made by several small concerns.

Billions of tons of phosphate rock that can be processed economically by present technologic methods are now believed to occur in Florida, where hitherto only a few hundred million tons had been estimated. New estimates, made by the phosphate-rock industry, quintuple the former estimates of land-pebble reserves, increase those of hard rock over 200 times, and add a billion tons for soft phosphate. The extensive but inadequately prospected Tertiary Hawthorne formation underlying the land-pebble field, which is known to carry high-grade phosphate rock in several spots, is also included in the estimates as a possible source of 20 billion tons of phosphate rock,

[7] Maynard, Poole, New Data on Our Phosphate Reserves: Chem. Ind., vol. 44, No. 1, January 1939, pp. 26–27.

Digitized by Google

making the estimated total reserves of Florida phosphate rock containing over 35 percent B. P. L. equal to 26 billion tons.

The results of Government prospecting on certain public phosphate lands in Florida were given in a press release [8] late in 1938.

Trends in the technology, employment, and output per man in the phosphate-rock industry in Florida since 1880 are covered in a recent report by A. Porter Haskell, Jr., and O. E. Kiessling.[9] The new phosphate plant of Swift & Co. was described by Trauffer.[10]

## SOUTH CAROLINA

After many years South Carolina again has become a producing State. In 1938, 100 tons of phosphate rock were mined and exported from the Coosaw River region by the General Phosphate Corporation.

As a result of recent technologic improvements in the manufacture of phosphoric acid and elemental phosphorus, phosphate rock of even lower average grade than that formerly produced in South Carolina is now utilized in both Florida and Tennessee, and the joint congressional investigating committee's report suggests that "the Nation's lesser deposits [of phosphate rock], such as those in Arkansas and South Carolina, should be developed and conserved in the principal interest of the areas immediately surrounding them."

The history of the phosphate-rock industry of South Carolina has recently been covered in an unpublished report by Helen F. Mappus.[11]

## TENNESSEE

Tennessee again established a new record in phosphate-rock production in 1938, the quantity and value of its shipments being greater than ever before. Brown rock was shipped from Maury, Giles, Davidson, and Williamson Counties. No blue or white rock was mined or shipped during the year. Total stocks of phosphate rock in producers' hands in Tennessee at the close of 1938 were somewhat lower than at the end of 1937.

*Tennessee phosphate rock sold or used by producers, 1934–38*

[1] Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.
[2] Includes sintered matrix.

In each year since 1935, six phosphate-rock mining companies (Armour Fertilizer Works, Charleston Mining Co., Federal Chemical Co., Hoover & Mason Phosphate Co., International Agricultural Corporation, and the Monsanto Chemical Co.) have, together with the Tennessee Valley Authority, produced 98 percent or more of the total annual production of Tennessee. In 1938 these seven producers contributed over 99 percent of the total for the State. The three leading producers—Charleston Mining Co., International Agricultural Corporation, and Monsanto Chemical Co.—furnished 63 percent of the State total in 1938.

Reports describing recent developments in the Tennessee phosphate-rock industry,[12] the Hoover & Mason plant,[13] and the technology, employment, and output per man in the Tennessee phosphate-rock industry, 1880–1937,[14] have been published lately.

The Victor Chemical Works completed the construction of its electric-furnace plant for the production of elemental phosphorus at Mount Pleasant, Tenn., and began operations June 1, 1938, the material for the furnace being furnished by the Charleston Mining Co.

Tonnage production of elemental phosphorus by the electric-furnace plant of the Monsanto Chemical Co., near Columbia, Tenn., has made available such quantities of pure dry phosphorus pentoxide that the price in carload lots was cut 33⅓ percent in 1938, or from 18 to 12 cents a pound.

Increasing quantities of low-grade phosphatic materials are being mined in Tennessee largely for use in the electric-furnace production of elemental phosphorus. In 1938, 39 percent of the total production of the State was brown rock or matrix containing less than 60 percent B. P. L. The Charleston Mining Co., Monsanto Chemical Co., and

Digitized by Google

the Tennessee Valley Authority produced this low-grade material for electric-furnace uses and the Harsh Phosphate Co. for fertilizer fillers.

New estimates [15] of the phosphate-rock reserves in Tennessee, made by the phosphate-rock industry, place the quantity at 5 to 6 billion tons of phosphate rock containing over 45 percent B. P. L. The new estimate of reserves of brown, blue, and white phosphate rock combined is only double the previous estimate of about 100 million tons, the increase being due to the inclusion of figures for white rock and much enlarged figures for brown rock. The big increase in the new estimate of total reserves, however, is due to the inclusion of more than 5 billion tons for the at present unworked phosphatic limestones of the Central Basin of Tennessee, now believed amenable to present-day flotation or calcination treatment to produce products suitable for furnace processes or acidulation. These limestones were not included in the previous estimate, as at that time they were not considered of commercial value.

Mining operations of the Tennessee Valley Authority were in progress in 1938 both on its own and leased lands in the brown-rock field. According to its annual report, the T. V. A. at the end of the fiscal year 1937–38 held phosphate leases on 11 properties totaling 1,999 acres in Maury, Sumner, and Perry Counties and owned fee simple title to or mineral rights in 1,825 acres in tracts in Maury and Williamson Counties. Some of the matrix mined for T. V. A. during 1938 was exchanged for sintered phosphate rock produced by the Monsanto Chemical Co., which was shipped together with the remainder of the rock mined and rock purchased to the Muscle Shoals (Ala.) plant of the T. V. A.

T. V. A. continued research on the production of concentrated phosphate fertilizers. A small commercial-size unit manufacturing calcium metaphosphate was operated successfully, and 4,246 tons of calcium metaphosphate were manufactured during the fiscal year, production at the end of that period being at the rate of 30 tons a day. During the year a third electric furnace of approximately the same capacity as each of the other two was put into operation, and a new phosphoric acid plant was completed and successfully operated. The furnaces produced phosphorus for the metaphos unit and phosphoric acid for 45,759 tons of concentrated superphosphate containing about 43 to 46 percent $P_2O_5$.

Several articles were published in 1938 covering T. V. A. phosphate operations.[16]

A report of the findings of an interdepartmental committee appointed by the Secretaries of Agriculture and Interior in response to a request of the Joint Congressional Committee on the Investigation of the Tennessee Valley Authority was released November 9, 1938. This report contained the results of a scientific survey and technical investigation of the phosphate purchases of the T. V. A.

### VIRGINIA

The Southern Mineral Products Corporation (a subsidiary of the Vanadium Corporation of America) operated its milling plant at Piney River, Nelson County, Va., and recovered apatite concentrates from nelsonite ore from its mines in Amherst County, Va. The quantity of apatite concentrates recovered, sales, and stocks on hand at the end of the year increased in 1938 over 1937.

### WESTERN STATES

In 1938 Idaho and Montana were the only phosphate-rock-producing States in the West. In Idaho there was only one producing company in 1938, as in recent years—the Anaconda Copper Mining Co., which operated its No. 3 mine at Conda, Caribou County. In Montana there were two producers—one large and one small. The Montana Phosphate Products Co., Trail, British Columbia, operated the Anderson mine near Garrison, Powell County, and United States Government Leases 076740 and 081920, supplying the requirements of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail. Some of the product from these operations was ground by William Anderson at the mill near Garrison for direct application to the soil. The Mineral Hill Mining Co. (Cronin and Crowley) in 1938 made a relatively small output from its mine near Avon, shipping its product to the Anaconda Copper Mining Co. fertilizer plant at Anaconda, Mont.

The mine at Cokeville, Wyo., was not operated in 1938, but in 1937 a carload of phosphate rock was taken from this mine and shipped to the T. V. A. plant at Wilson Dam, Ala., for experimental work.

Most western phosphate rock is processed chemically at the plant of the Anaconda Copper Mining Co. at Anaconda, Mont., and that of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail, British Columbia. Both plants treat the phosphate rock with sulfuric acid, producing "triple" (or "treble") superphosphate. The plant at Trail, because of its synthetic ammonia operations, also makes ammonium phosphate and mixtures of ammonium phosphate and ammonium sulfate. A considerable part of the Canadian product comes back to American farms and citrus growers in the Western States.

Phosphate rock from Idaho is also used for the production of phosphate chemicals, in pig-iron blast-furnace charges, for the preparation of ordinary superphosphate in California, and for direct application to the soil.

A few articles regarding the deposits and operations of the Western States were published during the year.[17]

The Joint Congressional Committee to Investigate the Adequacy and Use of the Phosphate Resources of the United States [18] recommended that—

[18] See footnote 1.

Digitized by Google

A plant for experimental, educational, and demonstration purposes be established in the vicinity of the vast western deposits of phosphate, in order that those resources which are mainly located on public lands be conserved and wisely used for the benefit of American agriculture. Until such plant can be established, we recommend that the Tennessee Valley Authority conduct experiments with western phosphate ores, with particular reference to combination of potash and phosphate fertilizer products suitable for western soils.

*Western States phosphate rock sold or used by producers, 1934–38*

| Year | Idaho | | | Montana | | | Total | | |

## FOREIGN TRADE[19]

*Imports.*—Imports of phosphate rock into the United States in 1938 were limited to 2 long tons of apatite from Brazil and 7,004 tons of phosphate rock, mostly from French Oceania (6,300 tons) and Netherland West Indies (Curaçao) (701 tons). Three tons came from British Malaya.

Curaçao phosphate rock is outstanding because of its low fluorine content (less than 1 percent). Jacob and others[20] state that—

In proportion to the phosphoric acid content, Curaçao phosphate contains less fluorine than any of the other calcium phosphate rocks for which data are available.

*Phosphate rock and phosphatic fertilizers imported for consumption in the United States, 1934–38*

Digitized by Google

*Exports.*—Exports in 1938 were a little over a million tons and slightly exceeded 1937, both in quantity and value. The average value per ton of exports of phosphate rock increased from $5.53 in 1937 to $5.82 in 1938. The phosphate rock exported in 1938 came from Florida, South Carolina, and the Western States. Figure 2

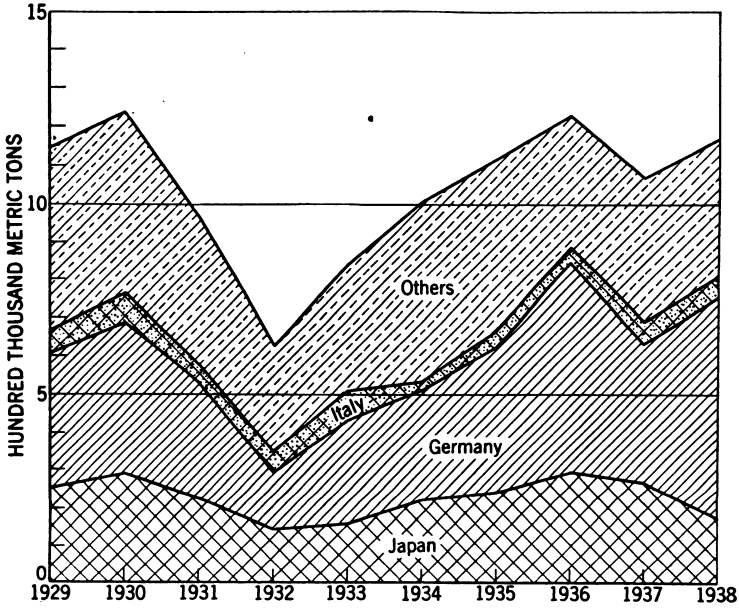

FIGURE 2.—Exports of phosphate rock from United States to Germany, Japan, Italy, and other countries, 1929–38.

shows the trends in total phosphate exports and in exports to the two largest importers of domestic phosphate—Germany and Japan—as well as to Italy.

*Phosphate rock exported from the United States, 1934–38*

| Year | Long tons | Value | | Year | Long tons | Value | |
|---|---|---|---|---|---|---|---|
| | | Total | Average | | | Total | Average |
| 1934 | 993,493 | $5,008,532 | $5.04 | 1937 | 1,052,802 | $5,818,231 | $5.53 |
| 1935 | 1,104,394 | 5,773,506 | 5.23 | 1938 | 1,140,841 | 6,637,638 | 5.82 |
| 1936 | 1,208,951 | 6,776,917 | 5.61 | | | | |

The quantity and value of exports of both hard rock and land pebble increased in 1938 over 1937. The quantity and value of exports of other phosphatic materials, principally sintered phosphate matrix, were less. The following tables show total exports of high-grade hard rock and land-pebble phosphate rock, as well as shipments of each type of rock to various countries from 1934 to 1938, inclusive.

[1] Less than 1 ton.

## WORLD PRODUCTION

World production of phosphate rock from 1934 to 1938, inclusive, is shown in the following table. Statistical details of world trade, production, and consumption of phosphate rock for 1935, 1936, and 1937 were published early in 1939.[21]

*World production of phosphate rock, 1934–38, by countries, in metric tons*

## INTERNATIONAL TRADE

Statistics on trade among the various countries producing or consuming phosphate rock in 1938 are shown in a table issued by the Phosphate Export Association (New York). Diagrams embodying some of the data are included in this chapter because of the current interest in the future of Tunisia. These diagrams show destinations of exports of phosphate rock from Tunisia (fig. 3), sources of French

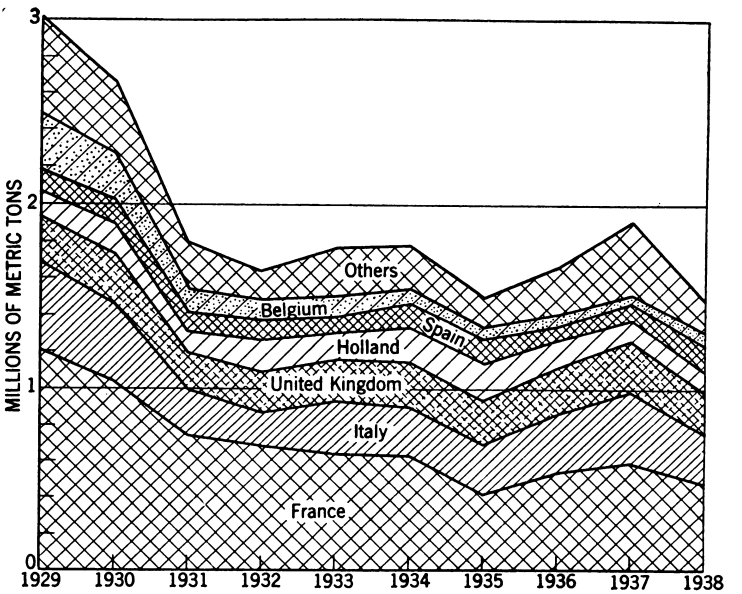

FIGURE 3.—Destinations of exports of phosphate rock from Tunisia, 1929–38.

phosphate-rock supplies (fig. 4), and sources of Italian phosphate-rock supplies (fig. 5).

## TECHNOLOGY

The reactions of calcined phosphate rock (obtained by heating silica-bearing phosphate rock at 1,400° C. in the presence of water) with ammonium sulfate and superphosphate are described in a paper by Beeson and Jacob.[22]

Results of a study of the treatment of phosphate rock with by-product hydrochloric acid for the production of monocalcium chlorophosphate, a potential fertilizer material, is given in a paper by Fox and Clark.[23]

Many data on the technology of the domestic phosphate-rock industry are contained in a report by Haskell and Kiessling.[24] Articles in recent issues of the Fertilizer Review [25] also contain data on the technology of phosphate rock.

## BASIC SLAG

Shortly after the introduction of the basic Bessemer process in 1878 for converting pig iron into steel and simultaneously removing the phosphorus, the slag produced in the process was used as a liming material for acid and lime-deficient soils. Later the effectiveness of the phosphorus in the slag was recognized, and basic slag is now an important competitor of phosphate rock and superphosphate as a source of fertilizer phosphorus in various European countries. Basic slag contains 5 to 20 percent available phosphoric acid, and that produced in this country is sold on the basis of a content of 8 percent total phosphoric acid.[27] The domestic market is limited and is satisfied by the importation of a small quantity and by an annual production of a few thousand tons in the Birmingham iron district of Alabama.

*Production of basic slag in Europe and the United States, 1934–37, in metric tons* [1]

# TALC, PYROPHYLLITE, AND GROUND SOAPSTONE[1]

By BERTRAND L. JOHNSON and K. G. WARNER

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1273 | Prices | 1277 |
| Salient statistics | 1274 | Developments in the industry | 1278 |
| Sales | 1274 | Foreign trade | 1278 |
| Markets | 1275 | World production | 1280 |

Reacting slightly from the all-time peak year of 1937, sales of talc, pyrophyllite, and ground soapstone in 1938 declined 17,000 tons. Total sales of 212,775 short tons valued at $2,302,560 compared favorably with the levels of recent years. Sales of ground materials decreased 20,000 tons, but this decrease was partly counterbalanced by increases in sales of crude and sawed and manufactured materials. Imports of crude materials were a little larger than in 1937, but those of manufactured products were considerably less. Exports of crude and ground talc, steatite, and soapstone decreased, but exports of talcum powders increased slightly.

Pyrophyllite is included in this discussion with talc solely because the custom was established many years ago in these annual reports of the Bureau of Mines. Although pyrophyllite resembles talc in certain physical properties, it is a hydrous aluminum silicate ($Al_2Si_4O_{10}(OH)_2$) instead of a hydrous magnesium silicate like talc ($Mg_3Si_4O_{10}(OH)_2$). Dana [2] and other mineralogists place pyrophyllite in a kaolin division containing the kaolin minerals—kaolinite, dickite, and nacrite—and the hydrous aluminum silicates—halloysite, allophane, beidellite, and montmorillonite. Schwartz [3] places it in a trivalent hydrous metadisilicate group with kaolin, montmorillonite, and certain other minerals. Pyrophyllite has a somewhat different composition and structure [4] from kaolinite ($Al_2Si_2O_5(OH)_4$).

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

[1] Includes crude value of some sawed material. [2] Quantity not recorded.

Nine States produced talc, pyrophyllite, and ground soapstone in 1938. Two of these States were on the Pacific coast; the others, producing most of the output, were in the East. Both talc and soapstone were produced in California, Maryland, Vermont, and Virginia; talc only in Georgia, New York, and Washington; talc and pyrophyllite in North Carolina; and only soapstone in Pennsylvania.

## SALES

Sales of talc, pyrophyllite, and ground soapstone, which totaled 212,775 short tons in 1938, were down from the peak of 1937 to the general zone of fluctuations that has marked the upper limit of sales during recent years. Decreases in total sales of more than 7 percent in quantity and 10 percent in value from 1937 reflected the decreased demand for ground talc. Sales of crude, as well as sawed and manufactured materials, increased.

*Talc, pyrophyllite, and ground soapstone, sold by producers in the United States, 1934–38, by classes*

| Year | Crude | | Sawed and manufactured | | Ground | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 8,767 | $55,659 | 174 | $46,918 | 129,564 | $1,346,108 | 138,505 | $1,448,685 |
| 1935 | 10,725 | 57,259 | 841 | 63,211 | 161,150 | 1,727,585 | 172,716 | 1,848,055 |

*Sales by States.*—Decreased sales in 1938 were reported by all the larger talc-producing States except Georgia, which has made a new high record every year since 1932 and in 1938 increased its sales 26 percent over the 1937 figure. Increases were also achieved in Mary-

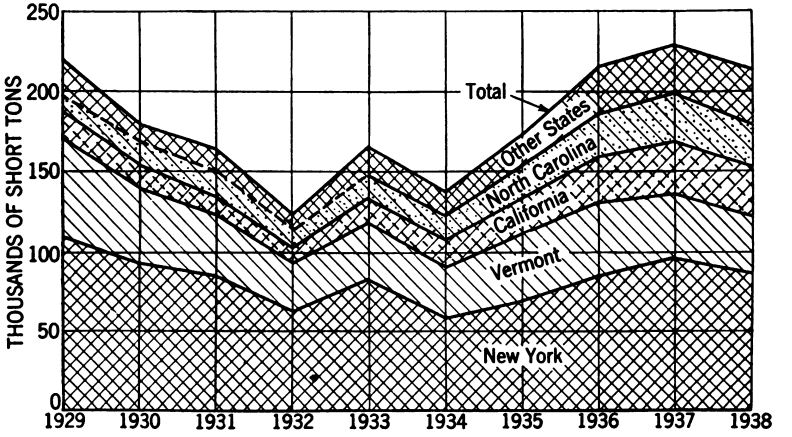

FIGURE 1.—Production of talc, pyrophyllite, and ground soapstone in the United States, 1929–38, by States.

land and Pennsylvania. Sales in both California and North Carolina dropped from the all-time highs of 1937.

## MARKETS [5]

The domestic market for talc, pyrophyllite, and ground soapstone is the largest in the world. It not only consumes most of the large domestic production of the crude material but also absorbs the hundreds of tons of foreign talc imported each year. In 1933, a depression year, domestic industries took 162,315 short tons of talc, pyrophyllite, and ground soapstone, principally of domestic origin, and in 1937, during a period of comparative prosperity, they required 221,445 tons. The market takes most of these materials in the ground state, 98 percent of the domestic sales of talc being ground material. Less than 1 percent is in the form of sawed and manufac-

[5] *See also* Johnson, Bertrand L., Marketing Talc, Pyrophyllite, and Ground Soapstone: Bureau of Mines Inf. Circ. 7080, June 1939, 13 pp.

Digitized by Google

tured material and the rest is crude. The largest markets for industrial-grade talcs are in the northeastern quarter of the United States and along the Pacific coast. Markets exist in many industries, principally, however, in the paint, ceramics, roofing, paper, and rubber industries, which in 1938 bought 77 percent of the total sales of domestic materials. Figure 2 shows the demand in the leading markets for the past 3 years.

Although consumption in the paint, paper, rubber, and several other industries declined in 1938, sales to the roofing industry increased 17 percent, and sales for toilet preparations—a minor outlet for domestic talc—jumped 38 percent. Paint manufacture is still the principal consumer, but the relative importance of other outlets has

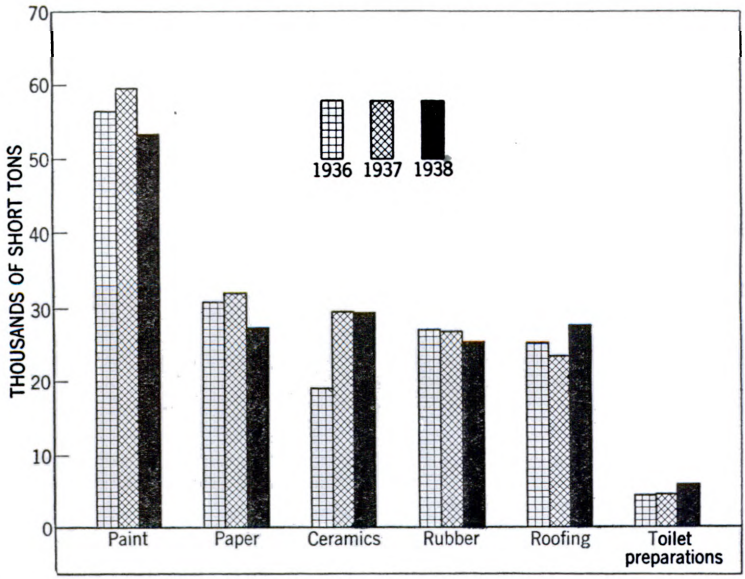

FIGURE 2.—Consumption of talc, pyrophyllite, and ground soapstone by leading consuming industries in the United States, 1936-38.

altered greatly. The ceramic industry, which took virtually the same quantity in 1938 as in 1937, is now in second place. Owing to an imposing gain, roofing climbed to third place, whereas it ranked fifth in 1937. Paper, formerly second, dropped to fourth position and rubber to fifth.

New York is the leading supplier of talc to the paint, ceramic, and paper industries, North Carolina to the rubber industry, and Vermont to the roofing industry. Pennsylvania led in supplying the needs for toilet preparations and Virginia in supplying those for foundry facings.

Almost 90 percent of the domestic talc used in paint in 1938 came from mines in New York; only minor quantities were shipped from other States, principally Pennsylvania, Vermont, California, and Maryland. New York's share of ceramic-talc sales was 48 and California's 30 percent; the remainder was chiefly pyrophyllite from North Carolina, although talc from Maryland, Vermont, and Washington also was used in ceramics. Vermont supplied about one-half of the talc used in roofing, the remainder coming from Georgia,

Digitized by Google

Virginia, Maryland, North Carolina, and Washington, in the order named. More than two-thirds of the talc taken by the paper industry came from New York and almost all the remainder from Vermont. Rubber manufacturers are large users of North Carolina pyrophyllite but also use substantial quantities of talc from Vermont, Georgia, and New York. Imported talc dominates the toilet-preparations industry, but Pennsylvania, California, and North Carolina shared in the increased sales of domestic raw material to this high-priced market in 1938.

[1] Includes crayons, bleaching, insecticides, plaster, textile, and other minor uses.

## PRICES

Talc is a relatively low priced commodity. The average value per ton of all grades of talc, pyrophyllite, and ground soapstone, f. o. b. mills, in the last few years, as reported to the Bureau of Mines by producers, has ranged from $10.43 to $12.50 a short ton. In 1938 it was $10.82. Lava-grade talcs and talcs suitable for making crayons bring the highest prices, generally $100 to $150 a ton. Prices for other kinds of domestic talc, pyrophyllite, and ground soapstone are much lower. Domestic ground talcs, except toilet grades, normally range in price from $4 to $20 a ton. Much domestic roofing talc (20- to 50-mesh) is said to have been sold as low as $4 a ton. Quotations on finer-ground domestic talcs, f. o. b. works, carload lots, were about as follows in 1938: Virginia talc, 200-mesh, $4.75 to $5.50, 325-mesh, $6.25 to $7; Georgia talc, 200-mesh, $6, 300-mesh, $7.50 to $10; Vermont talc, 200-mesh, $8 to $14; New York talc, 325-mesh, $11 to $17; California talc, $17 to $20. Ground soapstone from Virginia is generally quoted at $5 to $7 a ton, and that from Vermont at $10 to $12. Ground-pyrophyllite quotations range from $7.50 to $12 a ton. Prices of imported talcs range from $20 or less to $85 a ton, the higher prices being for Italian and French talcs.

## DEVELOPMENTS IN THE INDUSTRY

Recent plant developments in the pyrophyllite industry include the putting into operation in November 1937 [6] of the new plant of the Carolina Pyrophyllite Co. at Capyco, near Staley, N. C., and reported improvements at the plant of Standard Minerals, Inc., at Hemp, N. C.

The Carolina Pyrophyllite Co. obtains pyrophyllite from its mine, the Gerhardt deposit on Soapstone Mountain, about 4 miles west of the Capyco plant. The mine is operated as a glory hole with a shaft through which the material drops to a haulage tunnel. Trucks carry the pyrophyllite from the mine to the plant, where it is fed to a jaw crusher; the product is ground in Hardinge conical mills, after which it passes to Gayco air separators which can be set to produce any size of material from 60- to 325-mesh.

Inasmuch as the physical properties of pyrophyllite resemble those of ground talc, its early application was as a substitute for ground talc in many industries. In recent years, however, various percentages of pyrophyllite have been used as a ceramic-body ingredient in wall tile, in tableware, and as an addition in electrical porcelains. Stevens [7] has described its use as an electrical insulator and reports as follows:

> Pyrophyllite bodies compare favorably with porcelain in mechanical and electrical characteristics and may be used in applications where high puncture values or zero porosity are not prerequisites. Pyrophyllite is superior to porcelain in high-frequency applications, but it is inferior to steatite.

Parmelee and Barrett [8] have tested the pyrochemical properties of samples of North Carolina and Austrian pyrophyllite. Lintz [9] has discussed the use of talc and pyrophyllite in vitreous and semivitreous dinnerware bodies and concludes that a semivitreous dinnerware body can be developed by use of talc and pyrophyllite with a small percentage of whiting, the body having good drying and firing properties, high mechanical strength, and improved resistance to delayed crazing.

The use of pyrophyllite and talc as mineral fillers was discussed during the year in an article by Maynard.[10]

Investigations of the use of talc as a ceramic material still continue. Two papers by Thurnauer [11] discuss its use as a raw material for the manufacture of high-frequency insulators. In another paper Thurnauer [12] discusses the properties of cordierite-containing ceramic bodies with low thermal expansion, resulting from the firing of talc-kaolin mixtures.

## FOREIGN TRADE [13]

*Imports.*—Both the quantity and value of total imports of talc, steatite or soapstone, and French chalk declined in 1938. The quantity was less than in any year since 1934, and the value was less than

Digitized by Google

any year since the bottom of the depression in 1932. Declines were noted in imports from nearly all countries. Italy was again the leading source of supply, with Canada second and France third. Several tons of pyrophyllite were imported in 1938 from Manuels, Conception Bay, Newfoundland. In 1904 and 1905 a total of 7,750 tons were shipped from this deposit to the United States.

*Talc, steatite or soapstone, and French chalk imported for consumption in the United States, 1934–38*

| Year | Crude and unground steatite and French chalk | | Manufactures (except toilet preparations) wholly or partly finished | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 204 | $4,729 | 20,245 | $421,640 | 20,449 | $426,369 |
| 1935 | 298 | 5,856 | 23,598 | 486,418 | 23,896 | 492,274 |

*Talcum and other powders exported from the United States, 1934–38*

| Year | Description | Short tons | Value |
|---|---|---|---|
| 1934 | Talc, crude, in bulk | 4,903 | $83,530 |
| | Powders—talcum (in packages), face, and compact | (1) | 598,404 |
| 1935 | Talc, crude, in bulk | 5,814 | 101,290 |
| | Powders—talcum (in packages), face, and compact | (1) | 711,383 |
| 1936 | Talc, steatite, and soapstone, crude and ground | 6,670 | 115,434 |
| | Powders—talcum (in packages), face, and compact | (1) | 803,571 |
| 1937 | Talc, steatite, and soapstone, crude and ground | 8,878 | 149,625 |
| | Powders—talcum (in packages), face, and compact | (1) | 966,473 |
| 1938 | Talc, steatite, and soapstone, crude and ground | 7,118 | 124,194 |
| | Powders—talcum (in packages), face, and compact | (1) | 978,100 |

[1] Quantity not recorded.

## WORLD PRODUCTION

In 1938, as in previous years, the United States was the leading talc-producing country of the world, its production far exceeding that of other important producing countries, such as Canada in North America, China, and British India in Asia, and Austria, France, Germany, Italy, and Norway in Europe.

*World production of talc and soapstone, 1934–38, by countries, in metric tons*

| Imports | 1295 |

## FLUORSPAR

The year 1938, in vivid contrast to the statistical record for 1937, was one of sharply reduced demand for fluorspar. Consequently, production schedules at most domestic mines were suspended or curtailed, and imports declined substantially. Compared with 1937, consumption of fluorspar in 1938 decreased 41 percent, production 46 percent, shipments from domestic mines 56 percent, and imports 47 percent. Domestic shipments were the lowest since 1933 and imports the smallest since 1935.

In spite of the curtailment in fluorspar mining, considerable prospecting and development work were done, several new mines came into production, new milling plants were under construction or completed at three properties, and improvements were made at other mills.

Total sales of fluorspar to consumers in the United States were 99,478 short tons in 1938 (79,615 tons from domestic mines and 19,863 tons from foreign sources) compared with 215,744 tons in 1937 (180,744 tons from domestic mines and 34,970 from foreign sources). Total sales to the steel industry decreased to 62,196 tons in 1938 (161,306 tons in 1937), while sales to manufacturers of hydrofluoric acid declined to 20,976 tons (27,779 tons in 1937) and those to makers of glass and enamel dropped to 12,902 tons (19,507 tons in 1937).

Despite the lessened demand for fluorspar in 1938 the average composite selling price of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States was virtually the same as in 1937. The average selling price f. o. b. Illinois-Kentucky mines of fluorspar shipped to steel plants was $18 a short ton ($18.89 in 1937) and that of fluorspar shipped to manufacturers of hydrofluoric acid was $25.29 ($27.49 in 1937). The average selling price of imported fluorspar shipped to steel plants was $20.56 a ton at seaboard (duty paid) in 1938 ($22.04 in 1937) and that of fluorspar shipped to manufacturers of hydrofluoric acid was $27.54 a ton ($26.60 in 1937).

Under the Anglo-American trade treaty, the duty on fluorspar containing more than 97 percent calcium fluoride was decreased from $5 a short ton to $3.75 a ton, effective January 1, 1939.

[1] Figures not available.

Other important developments in 1938 were the initial importation of fluorspar from Mexico; first shipments of concentrates from the new flotation mill at Lordsburg, N. Mex.; exports of 541 tons to Japan; beginning of construction of flotation plants at Rosiclare, Ill., and Salida, Colo.; initial shipments by river and rail of fluorspar from Illinois to Atlantic coast consumers; and reduction of 23 percent in stocks of fluorspar at steel plants.

*Production and shipments.*—Fluorspar was known to have been produced in 1938 at 97 mines and prospects, and small quantities were recovered at an undetermined number of other prospects and reclaimed from mill ponds, waste dumps, and old workings of abandoned mines. All operations yielded about 99,000 short tons of merchantable fluorspar compared with about 183,000 tons in 1937. However, in spite of the large number of properties worked in 1938, 29 mines produced 88 percent of the total output.

Shipments of fluorspar from domestic mines in 1938 aggregated 80,403 short tons valued at $1,599,666, decreases of 56 percent in both quantity and total value from 1937. Shipments in 1938 were equivalent to 64 percent of the average annual tonnages shipped in the 5-year period 1926–30. Of the 1938 shipments, 20,862 tons were shipped by barge for delivery at upper Ohio River and tributary landings compared with 47,300 tons in 1937.

In 1938, mines operated by or for consumers shipped 13,226 short tons of fluorspar for use in their own plants compared with 31,700 tons in 1937.

Digitized by Google

The average value of all grades of domestic fluorspar shipped was $19.90 a ton ($0.33 less than the 1937 average). The value recorded for domestic fluorspar is the price paid f. o. b. mine shipping point and excludes cost of containers.

In 1938, 5 ounces of optical fluorspar were sold for $5.

The following table gives details of shipments of fluorspar by States for 1938 that may be published without revealing, except by permission, operations of individual producers.

*Fluorspar shipped from mines in the United States in 1938, by States*

| State | Gravel [1] | | | Lump | | |
|---|---|---|---|---|---|---|
| | Short tons | Value | | Short tons | Value | |
| | | Total | Average | | Total | Average |

| Production of basic open-hearth steel ingots and castings—long tons | 23,440,000 | 30,447,000 | 43,615,000 | 46,361,000 | 25,868,000 |
| Consumption of fluorspar in basic open-hearth steel production—short tons | 81,000 | 99,600 | 133,900 | 138,900 | 73,600 |
| Consumption of fluorspar per ton of steel made—pounds | 6.9 | 6.5 | 6.1 | 6.0 | 5.7 |
| Stocks of fluorspar on hand at steel plants at end of year—short tons | 45,500 | 47,500 | 59,200 | 71,400 | 55,000 |

The quantity of fluorspar used by individual plants per ton of basic open-hearth steel produced ranges from 1 to 50 pounds—a relatively small proportion of the furnace charge. The average is generally 5 to 8 pounds and dropped to 5.69 pounds in 1938 from 5.99 pounds in

Digitized by Google

1937. It is noteworthy that since 1921, the first year for which data were collected, the average consumption of fluorspar per ton of basic open-hearth steel made has declined almost steadily from 8.2 to 5.7 pounds. The following table shows the variation in average consumption of fluorspar per ton of basic open-hearth steel over a 5-year period in certain plants that make about 88 percent of the total.

*Average consumption of fluorspar per ton of steel, 1934–38, in pounds*

| 1934 | 1935 | 1936 | 1937 | 1938 | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|---|---|---|---|
| 14.443 | 13.243 | 13.187 | 13.867 | 12.548 | 7.488 | 7.048 | 6.734 | 7.360 | 8.420 |

*Quoted prices.*—In 1938 the quoted price f. o. b. Illinois-Kentucky mines for fluxing gravel fluorspar was $20 a short ton for rail delivery and $22 for barge delivery at Ohio River landings. Imported fluxing gravel fluorspar (at seaboard, duty paid) was quoted at $23.50 to $24 a short ton.

*Stocks at mines or shipping points.*—According to reports of producers the total quantity of fluorspar in stock at mines or shipping points at the close of 1938 was 82,679 short tons, or about 54 percent more than in 1937. These stocks comprised about 47,800 tons of crude fluorspar (calculated to be equivalent to 28,000 tons of ready-to-ship fluorspar) and 34,877 tons of ready-to-ship fluorspar.

*Stocks of fluorspar at mines or shipping points in the United States, Dec. 31, 1937 and 1938, by States, in short tons*

| State | 1937 | | | 1938 | | |
|---|---|---|---|---|---|---|

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

*Technologic developments.*—Commercial flotation of fluorspar in the United States is now about 10 years old; the process was first used commercially at Rosiclare, Ill., on March 18, 1929. Since that time plants have been completed and operated at Deming, Arrey, and Lordsburg, N. Mex., and Boulder, Colo. The mill at Boulder discontinued operations on fluorspar in 1937. Additional plants are under construction at Salida, Colo., and Rosiclare, Ill. Total output of flotation concentrates from 1929 through 1938 was 50,552 short tons.

Digitized by Google

Mitchell, Gross, and Oehler [1] have reviewed briefly the work of other investigators on froth flotation of fluorspar and have presented the results of their studies, the object of which was to determine some of the fundmental froth flotation properties of fluorspar and the associated gangue minerals, quartz and calcite. These investigators summarize their findings as follows:

A sample of table tailings from a fluorspar mill, containing a high percentage of calcite, was analyzed for particle size and mineral content. The minus 48-mesh portion was then used to study some of the froth flotation properties of fluorite and associated gangue minerals, quartz and calcite.

The best concentrates and the highest recoveries were obtained with cell temperatures of from 60° to 90° C.

The amount of reagents and the pH of the ore pulp were found to have pronounced effects on the recoveries obtained. About 1 pound of sodium carbonate per ton of ore proved to be the optimum amount. The best pH was 8.5. Water glass of 1.40 sp. gr. was used to the extent of 0.12 lb. per ton of ore. The consumption of fatty acid depended somewhat upon the amounts of other reagents used; too much fatty acid lowered the grade of concentrate.

Tap water proved to be fully as satisfactory as distilled water in these tests. Stearic acid was used as a collector in one run and gave results similar to those obtained with oleic acid.

Generally speaking, the smaller sizes were more easily floated. Fluorite coarser than 65-mesh was difficult to float. The best selectivity indices were obtained with material between 65- and 150-mesh in size.

Clemmer and others [2] have recorded observations and data obtained in applying selective flotation to several ores from the Cave in Rock (Ill.) district. Both batch and continuous tests are given to show the application of flotation to the production of lead, zinc, and fluorspar concentrates. Approximately 85 tons of fluorspar were collected during these plant tests. Of this amount, 38 tons averaged 98.01 percent $CaF_2$ and 47 tons averaged 95.22 percent $CaF_2$. According to these investigators:

The results of laboratory batch and pilot-plant tests, followed by larger-scale tests, have successfully demonstrated the feasibility of flotation for the concentration of southern Illinois lead-zinc-fluorspar ores. Although much work remains to be done before the ultimate metallurgical practice is established, the tests have shown that acceptable lead, zinc, and fluorspar concentrates may be produced with satisfactory recoveries.

If the middlings are to be marketed as metallurgical fluorspar, agglomeration such as briquetting or sintering probably will be necessary to make the product acceptable to steel makers. In fact, experiments on sintering fluorspar were conducted in 1938 by the Mahoning Mining Co., which reported that results of laboratory work and of a large-scale test on 150 tons were quite satisfactory, both from the standpoint of performing the sintering operation and of use of the product by an open-hearth steel maker.

Some results of studies by the Bureau of Mines on lead-zinc-fluorspar middlings from Mexico, Ky., and Cave in Rock, Ill., and on fluorspar concentrates from Wilmore, Ky., are given in a recent report.[3]

A method of removing fluorspar from zinc concentrates is the subject of United States Patent 2137600, dated November 22, 1938.

A few tests of a new electrostatic process for the separation of fluorspar and associated minerals were made during 1938.

## INDUSTRY IN 1938, BY STATES

*Arizona.*—Shipments of fluorspar from Arizona were 1,093 short tons in 1938 compared with 610 tons in 1937. Production in 1938 came from the Polly Ann and Daniel Camp mines, near Duncan, Greenlee County. Most of the fluorspar from the Polly Ann mine was shipped to domestic steel plants and to Japan. The fluorspar from the Daniel Camp mine and some from the Polly Ann mine moved to the flotation plants at Deming and Lordsburg, N. Mex. The flotation concentrates recovered from the fluorspar, instead of the run-of-mine material produced, have been credited to Arizona in the statistics.

*California.*—A plant for grinding fluorspar for the ceramic trade was constructed at West Berkeley the latter part of 1938.

*Colorado.*—Shipments of fluorspar from Colorado were 1,704 short tons in 1938 compared with 7,883 tons in 1937. Of the 1938 shipments, 1,465 tons went to steel plants, 135 tons to iron foundries, 44 tons to ferro-alloy plants, and 60 tons to hydrofluoric-acid plants. Shipments in 1938 comprised 104 tons from Boulder County and 1,600 tons from Chaffee County.

A mill comprising jigs and flotation machines was reported under construction by the Colorado Fluorspar Corporation, Salida, Colo.

*Illinois.*—Approximately 75,000 short tons of fluorspar-bearing rock, equivalent to 46,000 tons of merchantable fluorspar, were mined at 30 mines or prospects in 1938 compared with about 138,000 tons, equivalent to 81,000 tons of merchantable fluorspar, mined at 26 mines or prospects in 1937. Of the merchantable fluorspar produced in 1938, 38,000 tons were from mines where the fluorspar occurs in veins, chiefly in fault fissures, and 8,000 tons from mines where the fluorspar occurs in flat-lying tabular masses, locally called blanket formations.

Fluorspar-bearing material milled in Illinois in 1938 totaled 59,000 tons, from which 36,000 tons of fluorspar were recovered—a ratio of 1.639 : 1.

Shipments from Illinois were 35,368 tons in 1938 compared with 78,664 tons in 1937. Of the total, 13,572 tons were shipped by barge for delivery at upper Ohio River and tributary landings compared with 31,552 tons in 1937.

The Argo, Blue Diggings, Crystal, Daisy, Good Hope, Hamp, Hillside, Lee, and Spar Mountain mines supplied about 89 percent of the total merchantable fluorspar produced in Illinois in 1938. Most of the remainder came from the Boundary Shaft, Douglas, Humm, Lead Hill, Stewart, and Victory mines.

Development work at the Daisy mine in 1938 consisted of drifting 150 feet on the 800-foot level of the Daisy vein and driving a crosscut from the Daisy vein to the Blue Diggings vein which encountered 5 feet of good fluorspar. It was believed that the crosscut would show that the Daisy and Blue Diggings veins intersected at the 800-foot level. However, according to A. H. Cronk, the junction of the two veins has not yet been determined; in fact, the Blue Diggings vein shows indications of straightening, which would make the two veins meet below the 800-foot level. A considerable tonnage of acid-grade fluorspar was produced directly from the stopes on the Blue Diggings vein.

The Rosiclare Lead & Fluorspar Mining Co. made important additions to its power plant at Rosiclare. A new steel, brick, and concrete building was completed to house a 1,250-kilowatt and a 1,000-kilowatt turbine generator and two 600-horsepower boilers. Water for condensing purposes in the turbo-generators will be pumped directly from the Rosiclare mine by a 3,000-gallon-per-minute pump which has been installed in the Rosiclare shaft. The water in the Rosiclare mine will be lowered to approximately the 250-foot elevation, which will permit mining above this level on the Rosiclare vein. The Rosiclare mine has been inactive since January 1924, when it was flooded.

The Mahoning Mining Co. continued prospecting and development at its property about 8 miles north of Cave in Rock. Up to April 15, 1939, 125 churn-drill holes, 300 to 400 feet deep, had been put down and 2 shafts sunk. According to A. G. Johnson, mineralization in the new area now being developed does not appear to be as widespread as that in the section to the southwest near the escarpment. However, 3 bedded deposits have been located in an area about 1 mile square. One ore body occurs in the Fredonia limestone at the base of the Rosiclare sandstone, 1 in the Renault limestone at the base of the Bethel sandstone and 100 feet above the base of the Rosiclare sandstone, and 1 at the sub-Rosiclare horizon 50 to 60 feet below the base of the Rosiclare sandstone. Because of the prevailing dip (about 5°) of the formations to the northeast, the ore bodies lie much deeper than those to the southwest, but their fluorspar content is not as high. In addition to fluorspar, appreciable quantities of zinc, lead, and secondary quartz as well as smaller quantities of barite occur in the ore bodies, all more or less finely disseminated throughout the mass. In the ore body in the sub-Rosiclare horizon the lead-zinc content of the ore is high enough to be of economic importance. In the other 2 ore bodies it appears to be too low. The ore body in the sub-Rosiclare horizon has now been developed by a 300-foot shaft and several hundred feet of crosscutting. The ore body in the Renault limestone has been developed by a 160-foot shaft and 200 feet of drifting.

The Mahoning Mining Co. started construction at Rosiclare of a milling plant designed to treat 200 tons of lead-zinc-fluorspar ore in 24 hours; it is planned to have it in operation in May 1939. The plant will comprise a jaw crusher, a cone crusher, a vibrating screen, a ball mill, and three banks of flotation machines, one each for lead, zinc, and fluorspar. The fluorspar concentrates will be filtered and dried in a department separate from the flotation unit. Power for the plant will be supplied by the Rosiclare Lead & Fluorspar Mining Co. The crude ore will be trucked from the mine to the mill.

At the Victory mine 3,984 feet of diamond-core drilling was done in 1938.

At the Blue Diggings mine on the Blue Diggings vein, where the shaft was sunk from 538 to 720 feet in 1937, the 600- and 700-foot levels were driven north 160 and 600 feet, respectively, in a vein of fluorspar averaging 3 feet in width.

The 500-foot level of the Argo mine was driven north 380 feet and south 400 feet from the Blue Diggings-Argo crosscut. The vein of fluorspar in the north drift averaged 3 feet in width. The vein in the south drift started at a width of 2 feet but pinched out a short

Digitized by Google

distance from the crosscut. The drift was continued, and at slightly more than 200 feet from the crosscut a 2-foot vein was found which at 250 feet widened to 5 feet. At this point the drift broke through into a cavern 40 feet along the vein, 40 feet wide, and 90 feet high. The entire cavity was lined with marcasite studded with calcite crystals. The drift was continued along the east wall of the cavern in a 5-foot vein of fluorspar.

A new shaft 100 feet deep was sunk on the East-West vein at the Hamp mine. The 100-foot level was driven west 80 feet in low-grade ore. From this point a winze was sunk 60 feet in good fluorspar and a level driven west 100 feet.

Substantial improvements were made in the flotation mill of the Aluminum Ore Co. at Rosiclare.

Some development work was done at the Cave in Rock, Hardin Minerals, Jackson, Lacey, Pell, and Preen properties.

*Kentucky.*—Production of merchantable fluorspar in Kentucky was about 43,000 short tons in 1938 compared with 87,000 tons in 1937, and shipments were 34,803 tons compared with 87,296 tons in 1937. Of the 1938 shipments, 7,290 tons were shipped by barge for delivery at upper Ohio River and tributary landings compared with 15,748 tons in 1937.

Virtually the entire output of fluorspar in Caldwell County in 1938 came from the Hollowell & Hobby mine, near Princeton.

Production in Crittenden County, amounting to approximately 15,000 tons, came chiefly from the Bachelor, Beard, Butler, Davenport, Hodge, Keystone, Lafayette, Memphis, Pigmy, and Susie Beeler mines, which contributed about 85 percent of the output of Crittenden County. Production was 49,000 tons in 1937.

In Livingston County about 24,000 tons of merchantable fluorspar were produced in 1938 compared with 35,000 tons in 1937. The chief producing mines were the C. R. Babb, Klondike, and Nancy Hanks mines, which accounted for 93 percent of the output of Livingston County.

In 1938 the Faircloth mine near Wilmore, Woodford County, shipped 300 tons of fluxing-gravel and 150 tons of acid lump fluorspar, and the Twin Chimney mine near Mundys Landing, Mercer County, shipped 150 tons of fluxing-gravel fluorspar.

*Montana.*—The Boeing prospect near Austin, Lewis and Clark County, was being developed in 1938.

*Nevada.*—Shipments of fluorspar from Nevada were 2,909 short tons in 1938 compared with 2,544 tons in 1937. Of the 1938 shipments, 1,881 tons went to steel plants, 292 tons to glass and enamel makers, 686 tons to hydrofluoric-acid manufacturers, and 50 tons to cement plants.

The chief producing mine in Nevada in 1938 was the Baxter, in Mineral County, which shipped 2,142 tons. The other active mine was the Daisy, in Nye County, which shipped 767 tons, including 127 tons of ground fluorspar.

*New Hampshire.*—Fluorspar activity at the Stoddard mine near Westmoreland, Cheshire County, in 1938 was confined to milling some ore previously mined and to shipping 78 tons to steel plants and 12 tons to foundries.

*New Mexico.*—Shipments of fluorspar from New Mexico were 4,066 short tons in 1938 compared with 3,324 tons in 1937 and comprised

Digitized by Google

3,464 tons of high-grade flotation concentrates and 602 tons of metallurgical-grade fluorspar.

Production came chiefly from the Sadler mine in Luna County; Big Spar mine in Catron County; White Eagle, Shrine, Bitter Creek, and Rain Creek mines in Grant County; "Dean" mine in Hidalgo County; Lyda K mine in Sierra County; and Mallery mine in Valencia County.

Initial shipments of concentrates were made from the new flotation mill at Lordsburg.

The General Chemical Co., a large consumer of acid-grade fluorspar, acquired the flotation plant of the La Purisima Fluorspar Co. in October 1938; the mill capacity has been tripled.

*Utah.*—Shipments of fluorspar from Utah were 370 short tons in 1938 compared with 431 tons in 1937. Virtually all shipments in 1938 came from the Monarch claims in Beaver County; a little came from Tooele County. Of the 1938 shipments, 295 tons went to steel plants, 37 tons to foundries, and 38 tons to Japan.

At the Dalton property, also in Beaver County, development work was continued, in the course of which a small quantity of fluorspar was mined; a mill, consisting of rolls, a trommel screen, and a four-cell jig, was completed.

A small quantity of fluorspar was mined (but not shipped) at the Utah Fluorspar Co. property, also in Beaver County.

## OPTICAL FLUORSPAR

Optical fluorspar, which is rather rare and difficult to obtain, has been found occasionally in mines in the Illinois-Kentucky district, in the Central Kentucky district, and in some Western States, chiefly California. Although there is a limited market for flawless, transparent crystals of fluorspar, apparently the demand is only partly supplied from domestic sources. In 1938, for example, only 5 ounces of optical fluorspar valued at $5 were reported sold by domestic producers.

Lithium fluoride crystals, now made commercially in the United States, are reported to make an excellent substitute for optical fluorite.[4] These crystals are said to have optical characteristics similar to fluorite and to show transparency considerably farther in the ultraviolet.

## IMPORTS AND EXPORTS[5]

Imports of fluorspar for consumption in the United States in 1938 totaled 19,622 short tons (9,216 tons containing more than 97 percent and 10,406 tons containing not more than 97 percent calcium fluoride) valued[6] at $287,643, compared with 37,063 tons (10,248 tons containing more than 97 percent and 26,815 tons containing not more than 97 percent calcium fluoride) valued[6] at $397,627 in 1937. The value assigned to the foreign fluorspar in 1938 averaged $14.66 a ton. The cost to consumers in the United States also includes duty, loading

[4] Industrial and Engineering Chemistry, News Ed., vol. 16, No. 21, Nov. 10, 1938, p. 584.

[5] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce; those on exports supplied by the producers. No exports of fluorspar recorded by the Bureau of Foreign and Domestic Commerce.

[6] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

Digitized by Google

charges at the docks, ocean freight, insurance, consular fee, and freight from docks to consuming points. The duty on fluorspar containing more than 97 percent calcium fluoride was decreased from $5 a short ton to $3.75 a ton, effective January 1, 1939. The duty on fluorspar containing not more than 97 percent calcium fluoride remained $7.50 a short ton.

Of the 1938 imports, 52.8 percent was metallurgical gravel fluorspar, 0.5 percent ceramic ground fluorspar, and 46.7 percent acid lump fluorspar. The metallurgical gravel fluorspar was imported from France, Newfoundland, Spain, Tunisia, and the United Kingdom; the ceramic ground fluorspar from France and Germany; and the acid lump fluorspar from Germany, Mexico, Newfoundland, Tunisia, and the Union of South Africa. Imports were equivalent to 24 percent of the total shipments of domestic fluorspar in 1938 compared with 20 percent in 1937.

[1] Less than 1 ton.

The following table, compiled from data furnished the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1937 and 1938 and the selling price at tidewater (duty paid), irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1937

Digitized by Google

and 1938. The quantities in the following table are based on the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated. Stocks of foreign fluorspar in the hands of importers in the United States were 1,165 short tons at the close of 1938.

Producers of fluorspar reported exports of 788 short tons valued at $9,061 in 1938 compared with 456 tons valued at $9,091 in 1937. Of the 1938 exports, 247 tons went to Canada and 541 tons to Japan.

*Fluorspar reported by producers as exported from the United States, 1934–38*

| Year | Short tons | Value | | Year | Short tons | Value | |
|---|---|---|---|---|---|---|---|
| | | Total | Average | | | Total | Average |
| 1934 | 522 | $8,602 | $16.48 | 1937 | 456 | $9,091 | $19.94 |

| 1936 | 240 | 4,079 | 17.00 | | | | |

## WORLD PRODUCTION

The following table shows the production of fluorspar by countries from 1934 to 1938, inclusive, insofar as statistics are available. Complete returns for 1938 are not yet available, but except for the U. S. S. R. those for 1937 are nearly complete. If the output of the U. S. S. R. is estimated roughly at 70,000 tons in 1937, world production of about 522,000 metric tons is indicated, of which the United States furnished 32 percent, Germany 28 percent, the U. S. S. R. 13 percent, France 10 percent, and the United Kingdom 8 percent—a total of 91 percent.

*France.*—The production of fluorspar in France, which reached an all-time peak of 58,660 metric tons in 1930, declined to 14,100 tons in 1934, and many mines were closed permanently. Since 1935 several mines have been reopened, and production has advanced progressively to 51,430 metric tons in 1937, the latest year for which statistics are available. Production undoubtedly declined in 1938, partly because of decreased exports. In 1938, for example, imports of fluorspar into the United States from France were only 7,411 short tons compared with 14,158 tons in 1937.

*Production of fluorspar in France, 1930 and 1935–37, by Departments, in metric tons*

| Department | 1930 | 1935 | 1936 | 1937 | Department | 1930 | 1935 | 1936 | 1937 |

The present status of the French fluorspar industry has been discussed and the chief mines have been described by Chermette.[7]

The following notes pertaining to the Font-Sante, Garrot, and "Luc" mines in the Department of Var, which export to the United States, have been taken from the article by Chermette.

[7] Chermette, A., Le Spath-fluor français en 1938. (French Fluorspar in 1938): Mines, Carrières, vol. 17, No. 193, Paris, November 1938, pp. 1–13.

Digitized by Google

The Font-Sante mine suspended operations in 1933, after having exported 50,000 tons of fluorspar. In 1935 the mine was reopened and small shipments were made to the United States; in 1936 exports were increased. In 1937 the mine was operated at the rate of 1,200 tons monthly. Several veins are mined, of which one attains an average width of 4 meters (13.1 feet) over a length of 60 meters (197 feet). Fluorspar-bearing rock from the mine is sent to the washery by means of an aerial ropeway 1,800 meters (5,905 feet) long.

The Garrot mine, near the Font-Sante, was formerly active, but operations were suspended in 1932. The mine was reopened in August 1937. Mine equipment has been electrified and a modern washery is to replace the older plant. The equipment will handle a monthly production of 1,000 tons.

In 1937 a new mine at Luc was opened, and a production of 12 tons daily was attained. A washery of 15 tons daily capacity was being constructed.

*Germany.*—Germany is second only to the United States as a producer of fluorspar but it is the chief exporting country. In 1937, for example, production was 144,459 metric tons; and exports were 46,009 metric tons, of which 12,699 metric tons went to the United States. Fluorspar was produced at 36 mines in 1937—1 in Anhalt, 2 in Baden, 18 in Bavaria, 5 in Prussia, 3 in Saxony, and 7 in Thuringia. Figures on production are not yet available for 1938, but exports decreased to 27,316 metric tons, of which 2,812 metric tons went to the United States. No fluorspar from Germany was received in the United States from August 1938 to March 1939.

*Newfoundland.*—Shipments of fluorspar from Newfoundland in 1938 were 9,859 short tons, of which 1,404 tons of fluxing grade, 3,548 tons of acid grade, and 15 tons for experimental purposes went to the United States; 2,539 tons of fluxing grade, 1,116 tons of acid grade, and 1,237 tons of special-grade lump (93 to 95 percent $CaF_2$) went to Canada. Shipments were 9,346 short tons in 1937.

The geological features of the fluorspar deposits of Newfoundland, the veins, and the mining and milling practices have been described by Howse.[8] The paper is accompanied by a mill flow sheet of the St. Lawrence Corporation of Newfoundland, Ltd., and a map showing the fluorspar veins. The veins are described as follows:

> The veins vary in width from 6 inches to 14 feet of solid fluorspar, and in places a width of fluorspar and granite breccia up to 35 feet is to be found. The presence of included granite is often a deciding factor in the economic value of the vein. Up to the present time it has been the practice to mine those veins which have the smallest proportion of granite, as this lowers appreciably the cost of hand picking. The length of the veins, as exposed to date, varies from 7,700 feet in the case of the Blue Beach vein to 200 feet in the case of the smallest known veins of the area. However, it may be said that in no case has a fissure vein been followed along its entire course, or even until it has narrowed beyond the point of economic mining.
>
> The most promising veins known to date are the Black Duck, Iron Springs, Blue Beach, Tarefare, Director, Lord and Lady Gulch, Red Head, Doctor's Pond, Scrape, Hookey, Grassy Gulch, Little Salt Cove, Morris, New Morris and Blake's Brook. It is interesting to note that all the veins strike within 45° southeast and 45° northwest of the general strike of the granite stock.
>
> This vein [Black Duck] is the most extensively worked to date. It has been mined to a depth of 180 feet, and shaft sinking is now in progress to a greater depth. The vein pinches and swells, both horizontally and vertically, from 6 inches to 8 feet. The average width is 4 feet and at the 180-foot level it appears to be quite as strong as it is at the surface. The dip is vertical and the vein has been mined

[8] Howse, C. K., St. Lawrence Fluorspar Mines: Newfoundland Geol. Survey Inf. Circ. 4, 1938, pp. 26–32.

Digitized by Google

laterally for 450 feet, with no diminution in width laterally. The vein is made up practically of pure fluorite, the only gangue materials being small amounts of sulfides of copper and zinc and granite breccia. This breccia makes up the greatest part of the gangue and usually is easily hand-picked, leaving a very high fluorspar concentrate.

The Iron Springs vein, next to the Black Duck vein, is best developed to date. Sinking has continued from the surface to a depth of 55 feet, and a dam has been erected near its intersection with Salt Cove Brook. The fluorspar in this vein is of higher grade than Black Duck, as there is less included granite breccia. This vein can be mined and shipped, with very little hand picking, as acid-grade ore. It varies in width from 2 feet to 9 feet with very clean walls at all points investigated to date. The vein dips at an angle of 68°, and a shaft is now being sunk to the 100-foot level where drifting east and west will begin. Mining has been done for a distance of 450 feet along strike.

Other veins on which mining has been done by open-cut contract are: The Scrape from which about 300 tons have been extracted, Doctor's Pond from which about 800 tons have been taken, Hare's Ears from which 2,000 tons have been mined, Blue Beach which has been mined on the No. 2 and No. 3 veins, about 1,500 tons having been extracted. Contracting began in December 1936 on the Lord and Lady Gulch and New Morris veins. The fluorspar in these veins is not as high grade as that of the Black Duck and Iron Springs, though "steel grade" can be produced with a little hand picking.

*Tunisia.*—Production of fluorspar in Tunisia, which was inaugurated in 1937, increased from 1,676 metric tons to 2,060 tons in 1938. Imports into the United States in 1938 comprised 719 short tons of fluxing grade and 853 tons of acid grade.

*Union of South Africa.*—Production of fluorspar in the Union of South Africa advanced to 5,221 short tons in 1938 from 3,985 tons in 1937, owing chiefly to greatly increased exports to the United States and to demand from Japan.

## CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. It is used in the metallurgy of aluminum, in the manufacture of glass and enamels, and in insecticides.

Gibbs [9] has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite.

British Patent 463092 covers improvements in the manufacture and production of synthetic cryolite.

*Imports.*—The following table shows imports of cryolite into the United States in 1937 and 1938. As cryolite is mined only in Greenland, it is evident that importations credited to countries other than Greenland probably include artificial cryolite.

*Cryolite (natural and artificial) imported for consumption in the United States, 1937–38, by countries*

# FELDSPAR

By Robert W. Metcalf

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1297 | Technologic developments | 1303 |
| Salient statistics | 1298 | Nepheline syenite | 1304 |
| Domestic production | 1298 | Aplite | 1305 |
| Crude | 1298 | Volcanic ash | 1305 |
| Ground | 1299 | Foreign trade | 1306 |
| Grinding mills in the United States | 1301 | Imports | 1306 |
| Consumption and uses | 1302 | Cornwall stone | 1306 |
| Crude | 1302 | World production | 1307 |
| Ground | 1302 | | |

The quantity of feldspar sold or used in the United States dropped sharply in 1938. The tonnage of both crude and ground spar fell far short of the records realized in 1936 and 1937, but remained higher than in 1935 and compared favorably with the best predepression

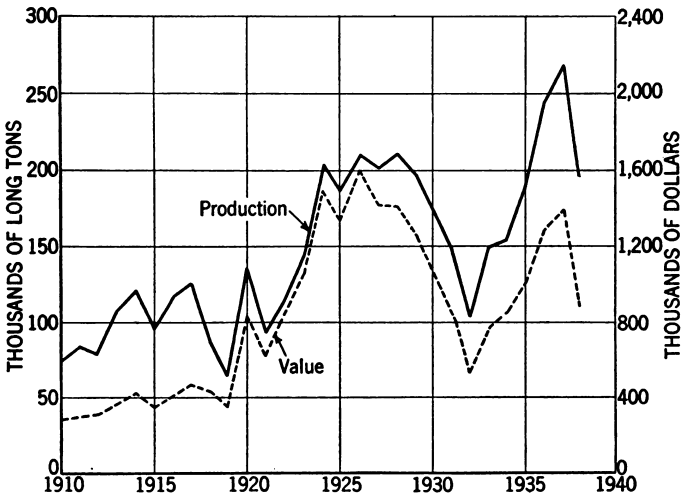

FIGURE 1.—Trends in production and value of crude feldspar in the United States, 1910–38.

levels. The average value per ton of the national output in 1938, however, was the lowest in many years.

Figure 1 shows trends in the domestic crude-feldspar industry since 1910.

Output of crude feldspar in 1938 amounted to 196,119 long tons valued at $895,081, a decrease of 27 percent in tonnage and 35 percent in value from 1937.

Continued experimentation with froth flotation and agglomerate tabling and a revival of investigations on electrostatic separation were of outstanding interest to the industry in 1938. Three mills are now processing nepheline syenite imported from Canada, and in

Digitized by Google

November a plant to produce a new fluxing material called "aplite," which has about the same alumina content as nepheline, was put into operation in Virginia. Two new feldspar grinding mills were either under construction or contemplated at the end of the year.

Low-cost western feldspar from South Dakota and Colorado contributed 36 percent of the total crude feldspar output in 1938. North Carolina retained its rank as the largest producing State, but South Dakota displaced Colorado as the second largest producer. All other States, except Arizona and Connecticut, reported decreases in crude-spar output in 1938 compared with 1937. Owing to the larger proportion of western feldspar, the average value per long ton of crude spar in 1938 decreased to $4.56, a drop of 12 percent from 1937.

Sales of ground feldspar by merchant mills in 1938 totaled 214,514 short tons valued at $2,466,252, a decline of 23 percent in tonnage and 29 percent in value compared with 1937. About 4 percent of the total feldspar ground in 1938 came from Canada.

*Salient statistics of the feldspar industry in the United States, 1937–38*

| | 1937 | 1938 | Percent change in 1938 |
|---|---|---|---|
| Crude feldspar: | | | |
| Domestic sales: | | | |
| Long tons | 268,532 | 196,119 | −27.0 |
| Value | $1,383,249 | $895,081 | −35.3 |
| Average per long ton | $5.15 | $4.56 | −11.5 |
| Imports: | | | |
| Long tons | 12,956 | 7,652 | −40.9 |
| Value | $91,885 | $56,133 | −38.9 |
| Average per long ton | $7.09 | $7.34 | +3.5 |
| Ground feldspar sold by merchant mills: | | | |
| Short tons | 279,272 | 214,514 | −23.2 |
| Value | $3,486,741 | $2,466,252 | −29.3 |
| Average per short ton | $12.49 | $11.50 | −7.9 |

## DOMESTIC PRODUCTION

In accordance with the usual practice in the industry, crude spar is reported in long tons of 2,240 pounds and ground spar in short tons of 2,000 pounds.

*Crude feldspar.*—In 1938, 196,119 long tons of crude feldspar worth $895,081 were sold or used in the United States, a decrease of 27 percent in tonnage and 35 percent in value from 1937. Owing to the relatively low value and greater output of western spar, the average sales realization in 1938 for the country as a whole dropped to $4.56 per long ton, the lowest figure since 1917.

*Crude feldspar sold or used by producers in the United States, 1934–38*

| Year | Long tons | Value | | Year | Long tons | Value | |
|---|---|---|---|---|---|---|---|
| | | Total | Average | | | Total | Average |
| 1934 | 154,188 | $853,136 | $5.53 | 1937 | 268,532 | $1,383,249 | $5.15 |
| 1935 | 189,550 | 1,005,021 | 5.30 | 1938 | 196,119 | 895,081 | 4.56 |
| 1936 | 244,726 | 1,303,090 | 5.32 | | | | |

Crude feldspar was produced commercially in 12 States in 1938, the same number as in 1937. No output was reported from Mary-

Digitized by Google

land, and Wyoming appears as a producer for the first time. North Carolina retained its rank as the largest producing State in spite of a drop in output to 56,795 long tons in 1938 from 94,595 tons in 1937 and 102,393 tons in 1936. South Dakota displaced Colorado as the second largest producer of crude spar and increased its output to 42,297 tons in 1938, 2 percent over the 1937 figure. Colorado's production, however, declined to 27,452 tons in 1938, or 35 percent below the 1937 figure. Substantial decreases were reported from all other States except Arizona and Connecticut. The output in Arizona, although small, increased considerably.

The average values per long ton f. o. b. mine in 1938 were $3.81 and $2.90 in Colorado and South Dakota, respectively, compared with $4.94 in Maine, $5.31 in New Hampshire, and $5.21 in North Carolina.

[1] Included under "Undistributed."

*Ground feldspar.*—Sales of ground feldspar in 1938 from 30 merchant mills declined to 214,514 short tons worth $2,466,252, 23 percent less in tonnage and 29 percent less in value than in 1937. The 30 mills (1 less than in 1937) represented 23 producing companies operating in 14 States. Western mills (two in Colorado and two in South Dakota) furnished 35 percent of the total ground spar sold in 1938 compared with 30 percent in 1937 and 23 percent in 1936. The combined share of North Carolina and Tennessee mills, on the other hand, represented only 29 percent of the total in 1938 compared with 33 percent in 1937 and 36 percent in 1936. Three mills grinding imported Canadian spar in 1938 produced about 4 percent of the total quantity of ground feldspar sold compared with four mills producing 6 percent in 1937. Additional quantities of domestic and perhaps imported spar are ground by certain companies for use in their own plants and are not included in the Bureau of Mines statistics, but the quantity is believed to be small compared with the output of merchant mills.

In 1938 South Dakota for the first time produced more ground feldspar than any other State, advancing from third place in 1937. As

Digitized by Google

recently as 1928, no spar was ground in South Dakota. Colorado was second in output, followed by North Carolina and Tennessee. Ground spar produced by Tennessee and North Carolina together totaled 61,467 short tons in 1938, 32 percent less than in 1937. Production in South Dakota in 1938 reached 42,489 tons, an all-time record for the State; and that in Colorado declined to 33,529 tons, a 23-percent decrease. Arizona, whose output may not be published, was the only State other than South Dakota that increased production over 1937. New Jersey's output declined 5 percent to 13,901 short tons. Other States reported sizable decreases in 1938 compared with 1937.

*Ground feldspar sold by merchant mills [1] in the United States, 1934–38*

[2] Included under "Undistributed."

The average value per short ton of ground feldspar produced by merchant mills in 1938 fell to $11.50, the lowest figure for many years, and ranged from $6.55 to $21.09 per ton in the various States. Sales realizations for Colorado and South Dakota in 1938 were respectively $6.55 and $7.07 compared with average values in the Eastern States as follows: New Jersey, $18.57; Tennessee-North Carolina, $13.37; Maine, $12.55; and Virginia, $13.19. Sales of ground feldspar manufactured from Canadian crude in 1938 averaged $19.26 per short ton compared with $18.86 per ton in 1937.

## CONSUMPTION AND USES

Although the bulk of the crude spar produced is processed by merchant mills, two sanitary-products manufacturers have their own quarries and milling equipment. A few miners of crude spar sell all or part of their higher-grade product in the crude state to soap and cleanser manufacturers, who use it after grinding as a mild abrasive in their products.

As heretofore, by far the larger part of the output of ground feldspar was consumed in the glass, pottery, and enamel industries. In 1938 glass manufacturers used 55 percent of the feldspar produced, pottery lines about 35 percent, and the enamel trades about 9 percent. The small remainder was used for miscellaneous purposes, chiefly ceramic.

*Ground feldspar sold by merchant mills in the United States, 1936–38, by uses, in short tons*

| Use | 1936 | | 1937 | | 1938 | |
|---|---|---|---|---|---|---|
| | Short tons | Percent of total | Short tons | Percent of total | Short tons | Percent of total |
| Ceramic: [1] | | | | | | |

| Pottery | 76,527 | 32.3 | [1] 102,346 | 36.6 | [1] 74,035 | 34.5 |
| Enamel and sanitary ware | 23,746 | 10.0 | [1] 25,111 | 9.0 | [1] 19,395 | 9.0 |
| Insulators and other porcelain goods | 5,105 | 2.1 | (1) | | (1) | |
| Brick and tile | 6,074 | 2.6 | (1) | | (1) | |
| Other ceramic uses | 1,839 | .8 | [1] 6,442 | 2.3 | [1] 2,077 | 1.0 |
| Soaps and abrasives | 1,328 | .8 | 1,653 | 1.2 | 1,207 | .6 |
| Binder for abrasive wheels | 584 | | 242 | | | |
| Other uses | 10 | | 1,450 | | | |
| | 236,890 | 100.0 | 279,272 | 100.0 | 214,514 | 100.0 |

[1] New classification for ceramic uses adopted in 1937 was as follows: Glass, pottery, enamel, and other ceramic. Except for glass, figures for 1937–38 are not directly comparable with those for earlier years.

All outlets for feldspar reduced their requirements in 1938. This slackening of demand is indicated by the 18-percent drop in production of glass containers in 1938 and the even greater decrease in output of plate and window glass. Output of porcelain-enameled flatware and sales of electric ranges and electric refrigerators for household use dropped sharply from 1937 levels. Production of bathroom accessories declined moderately.

## TECHNOLOGIC DEVELOPMENTS

In the earlier years of the feldspar industry neither producers nor consumers paid much attention to exact specifications, but as the ceramic and glass industries began to insist upon rigid chemical control of batch ingredients definite standards were developed for alumina, lime, and alkali content, as well as stricter limits for iron.

To meet these conditions the feldspar mills were remodeled; laboratory control was introduced, and arrangements were made for stocking different grades of spar and blending them into products of known and guaranteed composition. Almost before the industry had put its house in order, however, competition arose from other mineral products heretofore not on the market. These new materials, particularly nepheline syenite from Canada and, later, "aplite" from Virginia, were developed largely through the search for fluxes of higher alumina content for use chiefly in the glass industry. Increased consumption of talc and pyrophyllite in the manufacture of whiteware bodies and other ceramic products likewise has affected the use of feldspar.

Magnetic separators have been installed in the larger mills to insure a low-iron product. Other processing methods long employed in ore dressing are being adapted to beneficiate nonmetallic minerals. Froth flotation, in particular, is well suited to the purification of feldspar, quartz, clay, talc, nephelite, spodumene, and other ceramic raw materials. Cationic reagents, such as certain substituted ammonium compounds and nitrogen bases, seem especially useful in selectively filming acidic minerals including quartz, feldspar, mica, or other silicates.

Allied to froth flotation in principle but radically different in nature of equipment is agglomerate tabling. In this process, which successfully treats much coarser sizes than can be handled by flotation, the separation is made on a shaking table. The selectively oiled particles agglomerate into loosely adherent balls which are rolled across the riffled surface regardless of specific gravity. A quartz-feldspar mine at Keene, N. H., is using this method and is reported to obtain a feldspar containing less than 2 percent impurities and virtually pure quartz as a byproduct.

The use of highly selective methods allows separation of both soda and potash feldspars from the quartz.[1] For this operation the cationic reagents previously employed in Bureau of Mines research on nonmetallic mineral separations are supplemented by a newly discovered activator.

Electrostatic separation has been improved to afford another potentially commercial means of removing impurities from feldspar. Better methods of beneficiation and more efficient refining practice have made possible the treatment of lower-grade mixed feldspar-quartz rock and even the utilization of old dump material as a source of good feldspar. The making of clean, salable spar economically from previously worthless quarry waste, and even from granite, gneiss, or other relatively fine grained rock, is of major importance in the older feldspar-mining areas where the most-accessible pegmatite deposits

[1] O'Meara, R. G., Norman, J. E., and Hammond, W. B., Flotation and Agglomerate Separation of Quartz and Feldspar: Bull. Am. Ceram. Soc. (abs.), vol. 18, No. 4, April 1939, p. 127.

Digitized by Google

have been worked out and where recent competition from western spar and substitute materials has been most severe.

Results of an extensive field survey of the feldspar deposits of eight Virginia counties were published by the Virginia Polytechnic Institute.[2] Details of processes for purifying feldspar by magnetic separation have been described recently.[3] Direct determination of sodium oxide in feldspar was effected by Koenig.[4] Shelton[5] and Meyer reported on the effect of the rate of heating on the glass phase and the physical properties of whiteware bodies.

Utilization of iron- and steel-plant slag in glassmaking batches is reported from India.[6] Orthoclase feldspar combined with the slag, it is stated, makes a glass suitable for the manufacture of transparent as well as opaque and black bottles, jars, floor tiles, roof tiles, and other products. The large percentages of potash give good brilliance, and chemical durability is satisfactory owing to the almost equal proportions of potash and soda. Costs are claimed to be reduced about 50 percent as a result of the use of slag as a batch ingredient.

A German patent[7] describes the separation of mica and feldspar from the gangue rocks by a flotation process in which carbolic acid or creosote oil, a higher aliphatic acid or a salt thereof, and a terpineol are used together as flotation agents.

The economic significance of the feldspar deposits of middle, eastern, and southern Europe was described and production and export statistics were given by Kirnbauer.[8]

*Nepheline syenite.*—Three mills in the United States are now processing nepheline syenite for use in glass manufacture. Two of them—the American Nepheline Corporation, Rochester, N. Y., a subsidiary of Canadian Nepheline, Ltd., and the New England Nepheline Co., Keene, N. H., affiliated with Golding-Keene Co.—were in operation in 1937. The Oxford Mining & Milling Co., West Paris, Maine, a subsidiary of the United Feldspar Corporation, began grinding nepheline later. Crude rock for these mills is imported from Canada, mostly from Blue Mountain, Peterborough County, central Ontario, and from the neighboring counties of Hastings and Haliburton. Spence[9] has described the mining in this region and the processing both at Lakefield, Ontario, and at Rochester.

In wall tile and floor tile, according to Koenig,[10] the greater refractoriness of certain American clays is offset by additions of nepheline syenite, owing to its active fluxing action. Nepheline also permits the making of satisfactory floor-tile bodies at lower temperatures.

Crude nepheline syenite is bound free of duty in the Reciprocal Trade Agreement with Canada. There is a reservation, however, that if the imports of crude and ground material combined in any year exceed 50,000 tons the Canadian and the United States Governments will consult on measures to be taken. If no agreement is reached the United States reserves the right to impose a customs duty on imports in excess of the 50,000 tons stipulated. For the ground product this charge would be in addition to the present duty, which was reduced from 30 to 15 percent by the agreement.

*Aplite.*—In November 1938 another new high-alumina ceramic flux was made available to glass and pottery manufacturers. This material, known as aplite, which occurs near Piney River, Amherst County, Va., is a highly altered, white, massive rock consisting of albite and microcline feldspars, sericite, zoisite, clinozoisite, and other minerals. A typical analysis shows 59.80 percent $SiO_2$, 0.397 percent $Fe_2O_3$, 24.29 percent $Al_2O_3$, 5.86 percent CaO, 5.82 percent $Na_2O$, and 2.67 percent $K_2O$. Even with magnetic separators the iron content cannot readily be reduced below about 0.2 or 0.3 percent, which bars its use in clear-glass products but not in colored-glass containers, such as milk, liquor, and cosmetic bottles and similar glassware. The deposit, which apparently is quite extensive, is being developed by Dominion Minerals, Inc. Chemical and mineralogical content and physical properties of the rock were described in detail and the possibilities of its use for various ceramic purposes discussed by Dear and Whittemore.[11]

At the present stage of operation, until its iron content can be reduced further, aplite can be used in clear glass or white pottery only as a supplement to, rather than as a substitute for, feldspar. A blend of aplite and feldspar carries more alumina than the average commercial feldspar, but the proportion of aplite is limited strictly by the permissible iron content. Aplite, however, is cheaper than feldspar because it can be quarried by ordinary methods as it occurs in massive formations rather than in irregulr pockets in pegmatite veins or lenses.

*Volcanic ash.*—Further encroachment upon markets now supplied largely by feldspar is foreshadowed by recent tests of volcanic ash as a glaze constituent in glass batches. Plummer [12] reported the successful use of volcanic ash or pumicite in both fritted and raw glazes to replace the feldspar and part of the flint. Although in some of the glazes tested the ash content was more than 50 percent of the batch and the maturing temperature ranged from cones 09 to 8, no significant difference could be detected between the volcanic-ash glazes and control glazes of nearly identical chemical composition except the color effects due to the higher iron content of the pumicite.

The finely divided nature of the ash in its raw untreated state and its low cost, about $2 a ton, f. o. b., would be important factors in its possible utilization in glass batches and in colored glazes for roofing tile, wall tile, and low-priced pottery. About 1½ parts of the ash are said to be equivalent to 1 part of feldspar. Abundant supplies of nonweathered ash are available in southwest Kansas and northwest Oklahoma, particularly in McPherson County, Kans., and near Gate,

Okla. K. K. Landes, [13] assistant State geologist of Kansas, at Lawrence, recently has devoted much time and energy to the adaptation of volcanic ash to industrial use. Other selected references [14] may be of interest.

## FOREIGN TRADE

Effective January 1, 1939, under the Reciprocal Trade Agreement with Canada—virtually the only source of feldspar imports into the United States—the duty on crude spar was reduced to 25 cents a ton and that on ground spar to 15 percent. The rate on crude spar as specified in paragraph 207 of the Tariff Act of 1930 was $1 a long ton but was cut to 50 cents on January 1, 1932, by Presidential proclamation and to 35 cents under the first Canadian Trade Agreement. The latest 10-cent reduction brings the rate to only one-fourth of that provided in the Tariff Act of 1930 when the material was removed from the free list. Simultaneously, the Canadian duty on ground feldspar imported from the United States was lowered from 20 to 15 percent—the same rate as that levied on imports into the United States.

*Imports.*[15]—Both the tonnage and value of imports for consumption of crude feldspar in 1938, all from Canada, decreased approximately 40 percent—to 7,652 long tons worth $56,133 from 12,956 tons worth $91,885 in 1937. The average value per ton (foreign market value), however, increased to $7.34 in 1938 from $7.09 in 1937. In 1938, as in 1937, no ground feldspar was imported.

*Feldspar imported for consumption in the United States, 1934–38*

| Year | Crude | | Ground | | Year | Crude | | Ground | |
|---|---|---|---|---|---|---|---|---|---|
| | Long tons | Value | Short tons | Value | | Long tons | Value | Short tons | Value |
| 1934 | 9,744 | $67,258 | ------- | ------- | 1937 | 12,956 | $91,885 | ------- | ------- |
| 1935 | 8,937 | 56,175 | 1 | $106 | 1938 | 7,652 | 56,133 | ------- | ------- |
| 1936 | 10,786 | 68,198 | 132 | 1,276 | | | | | |

Probably owing to the increased use of natural or artificially blended materials of domestic origin, receipts of Cornwall stone receded sharply in 1938. Imports of the manufactured stone dropped to 513 long tons valued at $4,976, from 1,899 tons valued at $16,864 in 1937. Imports of ground Cornwall stone also decreased, amounting to 233 long tons valued at $1,797 compared with 323 tons valued at $4,267 in 1937. Crude and ground material originated in the United Kingdom in both 1937 and 1938.

## WORLD PRODUCTION

Sweden, Norway, China, and probably Czechoslovakia are the chief producers of feldspar aside from the United States. Smaller outputs regularly come from Germany (Bavaria), Italy, Rumania, Finland, Australia, and other widely separated countries. A large part of the Canadian crude-spar production is shipped to grinding mills in the United States for processing.

Available figures on world production of feldspar, 1934 to 1938, inclusive, follow.

*World production of feldspar, 1934–38, by countries, in metric tons*

[Compiled by M. T. Latus]

| Country [1] | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Argentina (shipments) | 431 | 495 | 1,082 | (2) | (2) |
| Australia: | | | | | |
| New South Wales [3] | 891 | 166 | 101 | 162 | (2) |
| South Australia [3] | 212 | 315 | 553 | 669 | (2) |
| Western Australia (exports) | 1,845 | 2,703 | 3,047 | 3,031 | (2) |
| Brazil | (2) | (2) | (2) | 8,400 | (2) |
| Canada (shipments) | 16,603 | 16,095 | 16,190 | 19,365 | 12,817 |
| China [4] | 27,780 | (2) | (2) | (2) | (2) |
| Egypt | | 72 | 45 | 158 | (2) |
| Finland (exports) | 3,329 | 2,071 | 2,520 | 3,232 | (2) |
| France | | | | 8,900 | (2) |
| Germany (Bavaria) | 6,808 | 6,337 | 9,524 | 9,986 | (2) |
| India, British | 638 | 713 | 798 | 495 | (2) |
| Italy | 7,637 | 7,616 | 8,620 | 13,437 | (2) |
| Norway (exports) | 22,139 | 24,228 | 29,985 | 32,555 | 21,761 |
| Rumania | 1,026 | 14,180 | 1,960 | (2) | (2) |
| Sweden | 34,468 | 48,637 | 56,799 | 49,140 | (2) |
| United States (sold or used) | 156,663 | 192,592 | 248,654 | 272,842 | 199,267 |

[1] In addition to countries listed, feldspar is produced in Czechoslovakia. Official figures of output are not available, but it is estimated that the annual production is approximately 30,000 metric tons. (Stat. Comm. Czechoslovak Ceram. Soc.)

[2] Data not yet available.

[3] Includes some china stone.

[4] Includes Manchuria.

Asbestos may be termed indispensable to modern life. As the chief constituent of brake-band linings and clutch facings it is essential to automotive transport; in the form of gaskets and packings it is a necessary part of steam-driven machinery; as a heat insulator it plays an important role in both household and factory construction and equipment; and combined with cement it is employed in the manufacture of vast quantities of roofing and other building materials.

The United States is the largest asbestos-consuming country in the world but produces only a small fraction of its requirements of raw materials. In 1938 domestic sales amounted to 6 percent of the quantity and 4 percent of the value of domestic requirements. How could our needs be met in an emergency?

Stimulation of domestic production bears little promise. Although many occurrences of chrysotile asbestos have been noted in the United States, few seem to have commercial possibilities. Arizona deposits furnish excellent crude fiber; but mining costs are high, transportation difficult, and freight rates to eastern markets excessive. Although Vermont deposits are extensive and can produce large quantities of mill fibers of moderate to short lengths, they furnish little fiber of spinning grade. Chrysotile deposits are known in California and some other States, but none appear to be capable of development into consistent producers.

The possibility of making synthetic asbestos to take the place of the natural fiber has been suggested; but, because of the special qualities of high-grade fiber that man cannot duplicate in a laboratory, the manufacture of a satisfactory product seems to be farther from attainment than the manufacture of synthetic diamonds.

Another alternative is substitution of other materials for the major uses of asbestos. Some progress has been made in this direction. Synthetic fibers such as mineral wool, slag wool, and glass wool, now made in large quantities, are related in no way to asbestos in composition yet have physical qualities that permit their employment in some fields of usefulness wherein asbestos has heretofore been used exclusively. In the heat-insulation field particularly the mineral-wool fibers have made some headway, but until it is demonstrated that they can be adapted to the other major uses the United States evi-

Digitized by Google

dently must continue to depend on foreign sources for its major supplies of asbestos.

The following table of salient statistics shows that domestic production in 1938 was 7 percent lower than in 1937. Asbestos sold or used by producers in 1938 decreased 14 percent in quantity and 28 percent in value compared with 1937. The large decline in unit value was due primarily to sales of an unusually high proportion of the shorter fibers produced in Arizona—a favorable development because heretofore sales have been confined principally to crudes on account of the high cost of transportation. With a well-equipped mill now catering particularly to the west-coast trade in shorter fibers, producers are provided with an avenue for sale of the lower-grade fibers that formerly were left on their hands. Compared with 1937, apparent consumption in the United States in 1938 dropped 41 percent in quantity and 42 percent in value.

| Exports of asbestos products | [1] | 3,047,078 | [1] | 2,533,916 |

[1] Figures not available.
[2] Bureau of Mines not at liberty to publish figures separately for chrysotile and amphibole.
[3] Quantity sold or used by producers, plus imports, minus exports.

Because of the interest that has lately been centered on strategic and critical minerals from a military standpoint and the fact that asbestos has been classed by the Army and Navy Munitions Board as a critical mineral, it seems fitting at this time to present a historic table comprising data on production and consumption for virtually half a century. Prior to 1890, the first year recorded in the table, asbestos had little industrial importance.

[1] Quantity sold or used by producers, plus imports, minus exports, except as indicated.
[2] Data on quantity of asbestos imported not available 1890–1912 and 1914.
[3] Asbestos sold or used by producers, plus imports; data on exports not separately recorded prior to July 1916.
[4] Bureau of Mines not at liberty to publish figures separately for chrysotile and amphibole.
[5] Figures not available.
[6] Export figures cover period July to December 1916.

*Consumption trends.*—The following table shows trends in the asbestos-products industries of the United States during recent years. The volume of asbestos consumed depends primarily on two great industries—automobile manufacture and the building trades. Although asbestos consumption made remarkable gains in 1937, outstripping both these consuming industries, the reversal in trend in 1938 was just as pronounced. As indicated in figure 1, only about

Digitized by Google

half as many automobiles were manufactured in 1938 as in 1937, and the moderate gain in building contracts failed to stem the downward trend in asbestos consumption that virtually paralleled the decline in output of automobiles.

*Raw asbestos consumed in the United States and asbestos products manufactured in and exported from the United States, 1933–38*

| Year | Raw asbestos—apparent consumption | Asbestos products— | | Year | Raw asbestos—apparent consumption | Asbestos products— | |
|---|---|---|---|---|---|---|---|
| | | Manufactured [1] | Exported [2] | | | Manufactured [1] | Exported [2] |
| | *Short tons* | | | | *Short tons* | | |
| 1933 | 122,909 | $44,644,270 | $1,743,140 | 1936 | 250,922 | (1) | $2,479,273 |
| 1934 | 123,752 | (1) | 2,142,514 | 1937 | 316,263 | $96,347,570 | 3,047,078 |
| 1935 | 174,655 | 62,420,944 | 2,261,929 | 1938 | 187,150 | (1) | 2,533,916 |

[1] Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets, packing, and similar products in which little asbestos was employed.
[2] Compiled from the records of the Bureau of Foreign and Domestic Commerce.

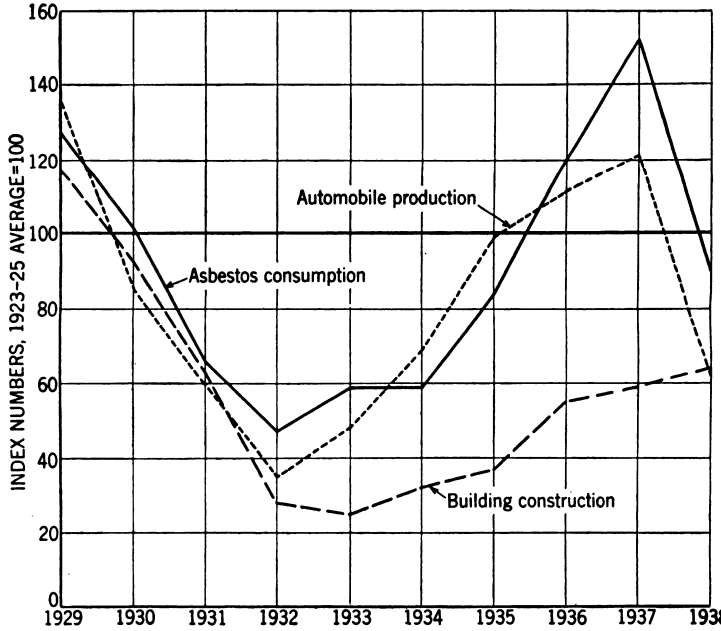

FIGURE 1.—Asbestos consumption compared with automobile production and value of building construction, 1929–38. Unlike units are reduced to percentages of the 1923–25 average. Statistics on automobiles are from the Bureau of the Census and building contracts from the Federal Reserve Board.

*Market conditions.*—The demand for asbestos in the United States was weak and hesitant throughout most of the year, although there was some evidence of improvement in November and December. European and Japanese markets were more active than those in America.

*Prices.*—All prices for asbestos are quoted on a short-ton basis. Canadian prices are f. o. b. Quebec mines, tax and bags included; Rhodesian, South African, and Russian, c. i. f. New York; and Vermont prices, f. o. b. mines, Vermont.

Digitized by Google

According to quotations in Metal and Mineral Markets, published by the McGraw-Hill Publishing Co., Inc., New York City, prices of Canadian asbestos were as follows: Crude No. 1, $700–$750; Crude No. 2 and sundry crudes, $150–$350; spinning fibers, magnesia, and compressed sheet fibers, $110–$200; shingle stock, $57–$77 ($78 in December); paper stock, $40–$45; cement stock, $21–$25; floats, $18–$20; and shorts, $12–$16.50.

Rhodesian Crude No. 1 was quoted at $275 and Crude No. 2 at $250 until March, when the prices were advanced to $300 and $260, respectively.

South African prices quoted since March 1938 are as follows: Amosite: Grade B 1 (white), $140; Grade B 3 (dark), $120. Transvaal Blue: Grade B (long fiber), $450; Grade S (short fiber), $140.

Russian Crude AA was quoted at $750; Crude No. 1, $275; Crude No. 2, $240; and shingle stock, $67.50 and up.

Vermont prices were constant throughout the year as follows: Shingle stock, $57; paper stock, $40; cement stock, $25; and shorts and floats, $12–$18.

## NEW DEVELOPMENTS

A decided increase in the use of molded brake linings in place of those made of asbestos fabric is to be noted. According to figures compiled by the Bureau of the Census, molded brake linings constituted 39 percent of the total footage in 1935 and 56 percent in 1937. One large manufacturer of asbestos products estimates that eventually molded linings may increase to more than 70 percent of the total. Recently a new type of die-formed molded lining made from woven fabric has been developed. Undoubtedly it has been devised by companies equipped for woven linings but desirous of entering the molded-lining field without discarding their present equipment.

A new type of cast pipe made of sulfur employs shredded asbestos as one of its constituents.

A sprayed coating for heat insulation, prevention of corrosion, and noise reduction consists of asbestos fibers and a bonding medium. These materials are projected against the surface in separate streams, and thus a feltlike coating is built up.

## REVIEW BY STATES

*Arizona.*—Both production and sales of chrysotile asbestos, chiefly from Gila County, made further gains in 1938. Sales were made by the Arizona Chrysotile Asbestos Co., Emsco Asbestos Co., and Arthur Enders, all of Globe, Ariz.; and Johns-Manville Products Corporation, New York, N. Y. Arthur Enders operates a mine on the Apache Reservation, under lease from the United States Government. According to report the fiberizing mill of the Emsco Asbestos Co. at Downey, Calif., has a capacity of 600 tons monthly.

*Maryland.*—The Powhatan Mining Corporation, Woodlawn, Baltimore, Md., produced amphibole asbestos near Pylesville, Harford County, and prepared it for use chiefly in filtering chemicals. For many years this material has been designated anthophyllite. Although some anthophyllite may be present in the deposit, the principal product has been identified definitely as tremolite.

Digitized by Google

*Vermont.*—The name of the company operating the well-known property at Eden, Lamoille County, has been changed to Vermont Asbestos Mines, division of the Ruberoid Co. (address 500 Fifth Avenue, New York, N. Y.). This company is the largest producer of asbestos in the United States.

*Other States.*—Plans are being made to resume operations at the Morgan asbestos mine in Placer County, Calif., and also for developing a property 9 miles from Glenrock, Converse County, Wyo. It has been reported to the Bureau of Mines that the Karstolite Co. no longer operates the anthophyllite deposit in Gallatin County, Mont.; but a new company, the Montana Asbestos Co., is in process of organization.

## FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States by countries and classes in 1937 and 1938. The total imports declined 42 percent in quantity and 41 percent in value. The decrease was shared by all countries furnishing substantial supplies except Italy, whose imports increased 59 percent. Imports from Cyprus fell from over 8,000 tons to an insignificant quantity.

## WORLD PRODUCTION

The following table shows world production of asbestos, by countries, from 1934 to 1938, insofar as figures are available:

*World production of asbestos, 1934–38, by countries, in metric tons* [1]

[Compiled by M. T. Latus]

| Country | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Argentina | ---------- | [2] 13 | ---------- | ---------- | (3) |

## CANADA

Sales of asbestos in Canada during 1938 declined 29 percent in quantity and 11 percent in value from the all-time high level of 1937. The entire production was from the Province of Quebec. The well-known deposits of this Province have been described in detail by Cooke.[2]

An improved all-metal standard testing machine recently devised retains the essential principle of the old machine.

In September 1938 it was reported that a new asbestos discovery had been made 260 miles north of North Bay, Ontario, but no details are available. Some publicity has been given to a new discovery on an island in Lake of the Woods, Ontario, but the material appears to be anthophyllite, which has little commercial importance at present. The following table shows sales in 1937 and 1938, as published in the Preliminary Report on the Mineral Production of Canada in 1938, issued by the Dominion Bureau of Statistics:

*Sales of asbestos in Canada, 1937–38*

| | 1937 | | | 1938 | | |
|---|---|---|---|---|---|---|
| | Short tons | Value | | Short tons | Value | |
| | | Total | Average per ton | | Total | Average per ton |
| Grade: | | | | | | |
| Crudes | 3,846 | $947,917 | $246.47 | 2,910 | $955,424 | $328.32 |
| Fibers | 200,247 | 10,235,820 | 51.12 | 163,182 | 9,714,509 | 59.53 |

| Rock milled | 5,440,607 | | | 4,874,548 | | |

## AFRICA

*Southern Rhodesia.*—The output of asbestos in Southern Rhodesia in 1938 exceeded by 3 percent the record production of 1937. The following table shows production during recent years:

*Asbestos produced in Southern Rhodesia, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 32,214 | £402,745 | 1937 | 57,014 | £840,025 |
| 1935 | 42,598 | 646,658 | 1938 | 58,811 | 1,020,921 |
| 1936 | 56,346 | 836,469 | | | |

*Union of South Africa.*—The output in the Union of South Africa in 1938 dropped 19 percent below that of 1937. Natal has again become a producer in a small way. The following table shows production during recent years:

[2] Cooke, H. C., Thetford, Disraeli, and Eastern Half of Warwick Map-Areas, Quebec: Canada, Dept. of Mines and Resources, Geol. Survey, Mem. 211, 1937, pp. 86–140.

| 1938 | 16,505 | 6,484 | [2] 187 | [2] 23,176 | [2] 416,401 |

[1] Small quantity of blue fiber from Transvaal included under Cape Province.
[2] Value of local sales plus value of exports.
[3] Small production in Natal in December 1936 and in 1937 included in 1938 figures.

The following table shows the tonnage of each variety produced from 1934 to 1938. A noteworthy feature is the striking decrease in chrysotile from Transvaal. This probably represents the effect of the reported early depletion of the Amianthus mine.

*Asbestos produced in the Union of South Africa, 1934–38, by varieties and sources, in short tons*

| Variety and source | 1934 | 1935 [1] | 1936 [1] | 1937 [2] | 1938 [2] |
|---|---|---|---|---|---|
| Amosite (Transvaal) | 3,757 | 4,684 | 4,823 | 6,531 | 8,793 |
| Chrysotile (Transvaal) | 11,025 | 15,483 | 16,149 | 16,855 | [3] 5,573 |

# BARITE AND BARIUM PRODUCTS [1]

By BERTRAND L. JOHNSON and K. G. WARNER

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1319 | Crude barite—Continued. | |
| Salient statistics | 1319 | Technology | 1323 |
| Crude barite | 1320 | Foreign trade | 1323 |
| Production | 1320 | World production | 1324 |
| Sales | 1320 | Barium products | 1325 |
| Prices | 1320 | Sales | 1325 |
| Consumption by uses | 1321 | Prices | 1326 |
| Consumption by States | 1322 | Preparation and uses | 1327 |
| Deposits | 1322 | Foreign trade | 1328 |

The demand for crude barite in 1938 was less than in 1937. Declines of 7 percent in production and 13 percent in sales were accompanied by a further rise in the average value of crude barite sold or used by producers (to $6.47). The increased demand for barite for use in well drilling failed to counterbalance the lessened demand for other barium products resulting from the general industrial depression. Imports of crude barite were less than half those of 1937, while the average declared value of the imported barite rose over a dollar a ton. Total sales of barium products were only slightly less in 1938 than in 1937, but the value was more than 2 million dollars lower owing largely to the slump in sales of lithopone and blanc fixe. The quantity of ground barite sold or used by producers increased markedly because of the demand from the petroleum industry, but sales of other barium chemicals, except the dioxide and hydroxide, decreased.

*Salient statistics of the barite and barium products industries in the United States, 1934–38*

| | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Crude barite: | | | | | |

## CRUDE BARITE

*Production.*—Barite-mining operations were in progress in 1938 in nine States—Arizona, California, Georgia, Missouri, Nevada, South Carolina, Tennessee, Texas, and Virginia. Arizona and South Carolina produced barite in 1938 but not in 1937. Mine production in 1938 totaled 335,433 short tons, a decrease of 7 percent from 1937 (360,877 tons).

*Sales.*—After increasing nearly 73,000 tons from 1936 to 1937, the quantity of crude barite sold or used by producers fell in 1938 more than 46,000 tons from the 1937 levels (see fig. 1), and the value decreased $236,449. The average value per ton of domestic sales rose from $6.30 (revised figure) to $6.47 in 1938 (see fig. 2), continuing the rise from the low 1933 level and bringing it up nearly to the 1930 level.

Missouri, as usual, was the leading State in sales of barite, with Georgia second, but both reported decreases in 1938 from 1937.

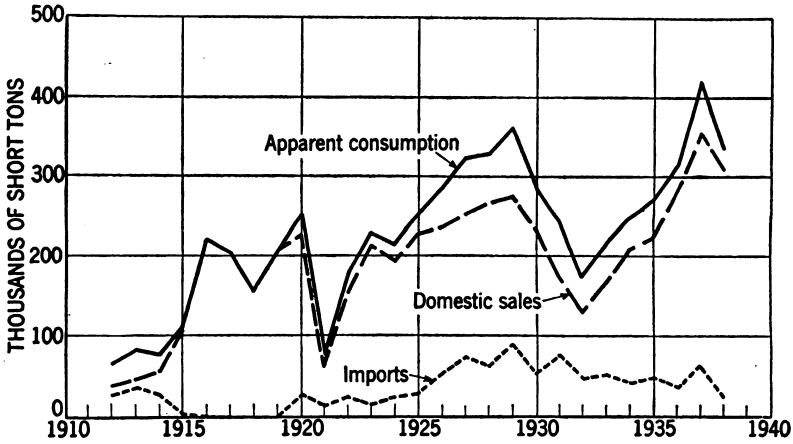

FIGURE 1.—Trends in domestic sales, imports, and apparent consumption of crude barite, 1912–38.

Sales were made by the same States in 1938 as in 1937, with the addition of Arizona and South Carolina and the elimination of Virginia. All the barite mined in Virginia in 1938 went into stocks.

*Crude barite sold or used by producers in the United States, 1937–38, by States*

| State | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| Georgia | 71,944 | [1] $400,687 | 64,304 | $315,329 |
| Missouri | 198,101 | 1,430,397 | 156,539 | 1,150,630 |
| Other States [2] | 85,843 | 409,886 | 88,820 | 538,562 |
| | 355,888 | [1] 2,240,970 | 309,663 | 2,004,521 |

[1] Revised figures.
[2] 1937: California, Nevada, Tennessee, Texas, and Virginia; 1938: Arizona, California, Nevada, South Carolina, Tennessee, and Texas.

*Prices.*—The market quotation for crude barite from Georgia, f. o. b. mines, according to the Engineering and Mining Journal Metal and Mineral Markets, has remained unchanged at $7 per short ton

Digitized by Google

from 1935 to 1938, inclusive. Missouri crude (93 percent barium sulfate, less than 1 percent iron) was quoted at $7.50 per short ton and crude barite (minimum 90 percent $BaSO_4$) at $6 to $6.50 f. o. b. mines in 1938. The average value, f. o. b. mine shipping point, of crude barite for the entire United States, as calculated from reports by producers to the Bureau of Mines, increased from $6.30 (revised figure) in 1937 to $6.47 in 1938.

*Consumption by uses.*—The consumption of crude barite (domestic and imported) in 1938 by manufacturers of barium products in the

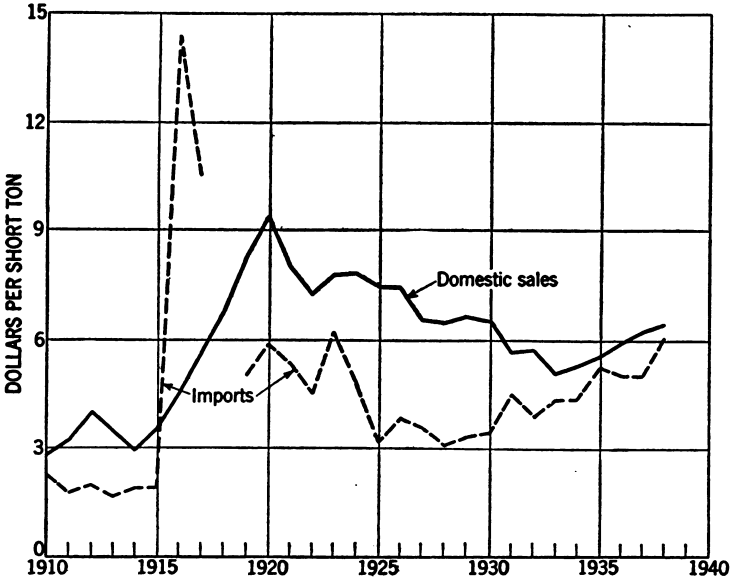

FIGURE 2.—Average value of domestic crude barite sold or used by producers and crude barite imported, 1910–38.

United States was about 19,000 tons less than in 1937, owing to large declines in the quantities of barite used in the manufacture of lithopone and barium chemicals that more than counterbalanced the large increase in the demand for ground barite. The upward trend in the quantity of crude barite used in the production of ground barite continued in 1938, with an increase of nearly 38,000 tons to a record total of 186,607 short tons. For the first time since 1916 more crude barite was used in the production of ground barite than in the production of lithopone. The quantity of crude barite consumed in lithopone production was less in 1938 than in any year since 1922.

*Crude barite (domestic and imported) used in the manufacture of barium products in the United States, 1934–38, in short tons*

| Year | In manufacture of— | | | Total | Year | In manufacture of— | | | Total |
|---|---|---|---|---|---|---|---|---|---|
| | Ground barite | Lithopone | Barium chemicals | | | Ground barite | Lithopone | Barium chemicals | |
| 1934 | 61,123 | 140,734 | 48,619 | 250,476 | 1937 | 148,930 | 162,681 | 72,371 | 383,982 |
| 1935 | 93,692 | 146,164 | 50,488 | 290,344 | 1938 | 186,607 | 117,007 | 54,250 | [1] 364,985 |
| 1936 | 83,990 | 167,014 | 52,445 | 303,449 | | | | | |

[1] Includes 7,121 short tons of crushed barite used in the glass industry.

Digitized by Google

*Consumption by States.*—Thirty-four plants in 13 States processed crude barite in 1938 compared with 31 plants in 12 States in 1937, producing ground barite, lithopone, and barium chemicals. The additional operations were in California (2), Missouri (1), and Rhode Island (1). One less plant operated in New York in 1938 than in 1937. These markets for crude barite lie in three general areas—the eastern or Atlantic Coast region, the midwestern or Mississippi Valley region, and the western or Pacific Coast region. The eastern and midwestern markets are by far the most important, each consuming 100,000 to 200,000 tons annually, whereas the western market consumes less than 60,000 tons. In 1938 a greater tonnage of crude barite was processed in the midwestern area than in the eastern, the Pacific Coast area still ranking third. Imports are confined largely to the Atlantic seaboard.

*Crude barite (domestic and imported) used in the manufacture of barium products in the United States in 1938, by States*

| State | Product manufactured | Plants | Barite used (short tons) |
|---|---|---|---|
| Missouri | Ground barite and chemicals | 5 | 122,921 |
| Delaware, New Jersey, and Pennsylvania | Lithopone and chemicals | 5 | 70,123 |
| California | Ground barite, lithopone, and chemicals | 8 | 57,930 |
| Illinois | do | 6 | 39,177 |
| Rhode Island | Chemicals | 1 | 67,713 |
| West Virginia | do | 2 | |
| Kansas | Lithopone | 1 | |
| Maryland | do | 1 | |
| Georgia | Ground barite and chemicals | 2 | |
| New York | do | 2 | |
| South Carolina | Ground barite | 1 | |
| | | [1] 34 | [2] 364,985 |

[1] A plant producing more than 1 product is counted but once in arriving at State totals.
[2] Includes 7,121 short tons of crushed barite used in the glass industry.

*Deposits.*—Several articles describing the barite deposits of Georgia, Tennessee, Virginia, and California were published in 1938.

The Cartersville barite district of Georgia was described by Kesler [2] and Hale.[3] Cartersville, the commercial center of the district, is on the western margin of a northeasterly trending mineralized belt 18 miles long by 2 miles wide. Crystalline barite of hydrothermal origin occurs in the highly fractured metamorphosed Shady dolomitic limestone of Lower Cambrian age. It fills fissures and forms irregular bodies, probably by replacement of the limestone. The Lower Cambrian rocks were folded and converted to low-grade metamorphic rocks during Appalachian mountain building near the end of Paleozoic time. Subsequently pegmatites were intruded, and hydrothermal solutions formed the mineral deposits of the district. Weathering of the dolomite by meteoric agencies followed the removal of the overlying rocks after Paleozoic times, and the commercial deposits of barite, rather definitely localized, occur in the residuum.

[2] Kesler, T. L., Sienna ("Ocher") Deposits of the Cartersville District, Ga.: Econ. Geol., vol. 34, No. 3, May 1939, pp. 324-341.

Digitized by Google

The barite deposits of Tennessee were discussed in several articles [4] in 1938. Tennessee has two important barite-producing areas—the Sweetwater district in eastern Tennessee and the Pall Mall district in central Tennessee. In the Sweetwater district the commercial barite deposits occur as lumps and masses of barite in the residual clays overlying the Knox (Cambro-Ordovician) dolomite, the barite being derived from the weathering of barite-bearing veins in the dolomite. In the Pall Mall district the commercial ores occur in the residual clays derived from the underlying upper Mississippian limestone.

Edmundson [5] described in detail the numerous barite deposits of Virginia. The barite occurs in fissure veins, replacement masses, breccia zones, and residual deposits. The wall rocks of the deposits include pre-Cambrian marble, schist, and gneiss; Paleozoic limestone and dolomite; and Triassic shale, sandstone, and diabase. Many of the deposits extend to a depth of 150 feet. The barite is believed by Edmundson to have been formed by rising solutions of magmatic origin. It is not thought that all the barite deposits were formed at the same time, but it is believed that the mineralization took place after the Appalachian revolution and may be related to Triassic igneous activity.

The occurrence of barite in California was described by Pabst.[6]

*Technology.*—The technologic treatment of various eastern and midwestern barite ores is discussed in recent reports.[7]

*Foreign trade.*—A considerable tonnage of crude barite is imported annually into Atlantic coast ports. The general trend of these imports since 1929 has been downward (see fig. 1), accompanied by a rise in average value that in 1938 reached $6.09 per ton (see fig. 2). All imports in 1938 (only 38 percent of those in 1937) were of German and Cuban barite, and although nearly five times as much barite entered from Cuba in 1938 as in 1937 the great decrease in imports from Germany lowered the total sharply. In 1938, 74 percent of the imports originated in Germany (partly transshipped from the Netherlands) and the rest in Cuba. Total imports of crude barite were the smallest since 1924.

Barite deposits in the Province of Pinar del Rio, Cuba, were worked during 1937 to supply demand in the United States, which did not, however, become as important as was anticipated. Exploitation of these deposits stimulated interest in other deposits of barite, but owing to lack of demand no additional production is known to have resulted.[8] No data are available regarding developments in 1938.

| | 64,992 | 327,224 | 24,845 | 151,235 |

Exports of crude barite from the United States are not separately recorded.

*World production.*—Barite is produced in many countries. Germany and the United States are by far the outstanding producers. In 1937 the United Kingdom, Italy, Greece, and France ranked next in order of output.

*World production of barite, 1934–38, by countries, in metric tons*

[1] Data not available.
[2] Official figures which, it is reported, cover only output of mines included under the mining law.

Germany [9] is the leading world producer of barite, furnishing about one-half of the total world output. The principal barite deposits are at Bad Lauterberg on the southern rim of the Harz Mountains massif. One-half the German barite production comes

[9] Redecker, S. B., American consul, Frankfurt-am-Main, Germany, German Production of Barium Materials: Consular Rept., Mar. 21, 1930, 8 pp.

Digitized by Google

from this region. Another leading center of production is Nordhausen in the Harz Mountains. Germany's consumption of barite has expanded markedly in recent years as a result of heavily increased demand for barite and its derivatives in the manufacture of pigments, paints, ceramics, waterproofing and softening agents, explosives, paper, rubber goods, and other commodities. Domestic consumption of barite in pigments has increased in recent years because of official requirements for mixing the cheaper and abundantly available barium sulfate with red lead, of which there has been a shortage in Germany, and thus extending the supplies of red lead.

In international barite trade Germany holds an even more important position than in barite production, as over half of the large German production is exported. Germany likewise has an extensive foreign trade in barium chemicals, especially lithopone, blanc fixe, artificial barium carbonate, barium chloride, and barium nitrate. Germany's export trade in barite and barium materials recorded favorable development from 1935 to 1937, but a considerable recession occurred in 1938.

## BARIUM PRODUCTS

*Sales.*—Because of the increased demand from the petroleum well-drilling industry, sales of ground barite were much greater in 1938 than in 1937. Sales of lithopone, blanc fixe, and artificial barium carbonate followed the general industrial decline and decreased in 1938; however, sales of other barium chemicals increased. Detailed statistics of sales of barium products during the past 5 years are given in the following table.

*Barium products sold or used by producers in the United States, 1934–38* [1]

| Product | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|
| Ground barite: | | | | | |
| Plants | 13 | 11 | 13 | 12 | 14 |
| Short tons | 53,326 | 76,250 | 69,102 | 129,777 | [2] 161,422 |
| Value | $1,006,905 | $1,407,787 | $1,217,818 | $2,249,612 | [2] $2,786,823 |

| Plants | 4 | 3 | 3 | 3 | 4 |
| Short tons | 4,706 | 7,329 | 11,347 | 10,755 | 9,543 |
| Value | $245,315 | $357,585 | $515,624 | $511,357 | $459,901 |
| Other barium chemicals: [3] | | | | | |
| Plants | 7 | 5 | 7 | 6 | 5 |
| Short tons | 7,084 | 7,520 | 8,893 | 8,632 | 10,963 |
| Value | $601,346 | $642,576 | $698,942 | $796,988 | $728,896 |
| Total barium products: | | | | | |
| Short tons | 228,796 | 268,652 | 263,810 | 332,185 | 327,102 |
| Value | $15,173,923 | $16,858,413 | $16,299,448 | $17,242,511 | $14,871,835 |

[1] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.

[2] Includes crushed barite used in the glass industry.

[3] Figures cover chemicals, in order of value, as follows—1934–35 and 1937: Chloride, dioxide, sulfide, and hydroxide; 1936 and 1938: Chloride, dioxide, sulfide, hydroxide, and oxide.

Lithopone is the most important single chemical made from barium sulfide. The combination of solutions of barium sulfide and zinc sulfate yields lithopone as a white intimate mixture or coprecipitate of

Digitized by Google

zinc sulfide and barium sulfate. Lithopone is used principally in the paint industry. (See fig. 3.) Sales for this purpose constituted over 81 percent of the total sales in 1938. Smaller quantities are consumed

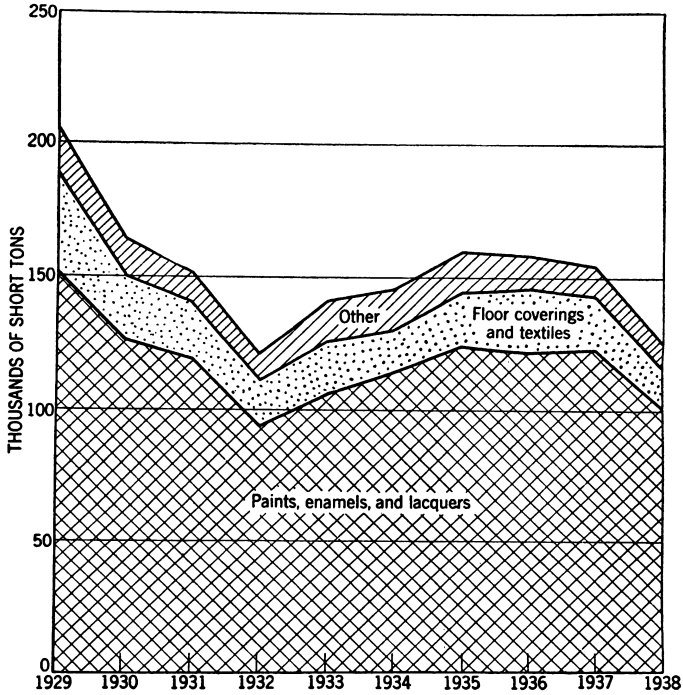

FIGURE 3.—Lithopone sold or used by producers, 1929–38, by consuming industries.

by the floor covering, textiles, and rubber industries. Sales of lithopone for all major uses decreased in 1938.

*Lithopone sold or used by producers, 1936–38, by consuming industries*

| Industry | 1936 | | 1937 | | 1938 | |
|---|---|---|---|---|---|---|
| | Short tons | Percent of total | Short tons | Percent of total | Short tons | Percent of total |

| Floor coverings and textiles | 23,085 | 14.6 | 20,194 | 13.1 | 15,400 | 12.2 |
| Rubber | 4,908 | 3.1 | 4,383 | 2.8 | 3,148 | 2.5 |
| Other | 7,865 | 5.0 | 7,279 | 4.7 | 5,274 | 4.2 |
| | 158,319 | 100.0 | 154,771 | 100.0 | 125,746 | 100.0 |

*Prices.*—Quotations for ground barite were the same in 1938 as in 1937. For ground witherite, however, prices were down somewhat from 1937, although those for precipitated barium carbonate were unchanged. Lithopone quotations showed slightly lower limits, in most instances one-eighth cent less. Lower prices also were quoted for barium nitrate. Prices for barium chloride had a smaller range, the lowest price quoted during 1938 being $77 compared with $74 in 1937. Details are given in the accompanying table, quotations being taken entirely from Chemical Industries.

[1] Chemical Industries (formerly Chemical Markets), New York (monthly).
[2] 90 percent.
[3] Lowest price for pulp grade, highest for high-grade precipitated.

*Preparation and uses.*—Crude barite ($BaSO_4$) is the raw material used in the preparation of most barium products. The treatment accorded to the barite in the manufacture of these various barium compounds is either (1) physical—grinding and refining for the production of crushed or ground barite —or (2) chemical—the furnace reduction of the barite with carbon, leaching of the "black ash" produced, and recovery of barium sulfide solution, which is used as the base for the preparation of various other barium chemicals, such as the sulfate, carbonate, chloride, and oxide.

Ground barite is used principally as a heavy medium in mud in the drilling of deep oil wells where high gas pressures are encountered. This use took nearly 80 percent of the total sales of ground barite in 1938. No other use takes over 5 percent of the total sales. The accompanying table shows the quantity and percentages of ground or refined barite sold or used by producers in 1938 by consuming industries; these data are available this year for the first time. Another important barium chemical is precipitated barium sulfate, known commercially as "blanc fixe." It is a very fine grained white powder, ordinarily prepared from a solution of barium sulfide by the addition of sodium sulfate (salt cake) but also obtained as a byproduct in the manufacture of hydrogen peroxide by the use of barium peroxide. Witherite, natural barium carbonate, is sometimes the raw material for its preparation. Blanc fixe is used as a filler, as a pigment in paints, in cosmetics, in paper manufacture, and for barium meals in X-ray photography.

*Ground or refined barite sold or used by producers in 1938, by consuming industries*

| Industry | Short tons | Percent of total | Industry | Short tons | Percent of total |
|---|---|---|---|---|---|
| Well drilling | 126,697 | 79 | Other [1] | 13,576 | 8 |
| Paint | 8,227 | 5 | Not reported | 2,015 | 1 |
| Glass | [2] 7,963 | 5 | | | |
| Rubber | 2,944 | 2 | | [2] 161,422 | 100 |

[1] Includes barite used in making paper, oilcloth, linoleum, cloth, and sugar, as well as minor quantities used in other industries.
[2] Includes some crushed barite used in the glass industry.

Digitized by Google

The following list includes producers of blanc fixe reporting production to the Bureau of Mines in 1938:

Barium Products Co. Ltd., Modesto, Calif.
Barium Reduction Corporation, South Charleston, W. Va.
E. I. du Pont de Nemours & Co., Room 10032, du Pont Building, Wilmington, Del.
Hercules Powder Co., Providence Drysalters Division, Wilmington, Del.
National Lead Co., Titanium Division, 111 Broadway, New York, N. Y.
Oakland Chemical Co., 59 Fourth Avenue, New York, N. Y.
Standard Ultramarine Co., Huntington, W. Va.

*Foreign trade.*—Imports of all classes of barium compounds for consumption in the United States in 1938 decreased both in quantity and value from 1937, except "barium compounds not elsewhere specified." Less than half the quantity of witherite was imported in 1938 as in 1937.

*Barium compounds imported for consumption in the United States, 1934–38*

# POTASH

By J. H. Hedges

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1329 | Government activities | 1333 |
| Salient statistics | 1331 | Review by States | 1334 |
| Prices | 1331 | Foreign trade | 1335 |
| Consumption and uses | 1332 | World production | 1337 |
| Production and sales | 1332 | Foreign developments | 1339 |

Producers in the United States made and sold more potash salts in 1938 than ever before, although both domestic consumption and exports receded from the 1937 peak. Imports dropped 45 percent to 193,609 tons $K_2O$ in 1938 from 351,445 tons $K_2O$ in 1937, but importers appear to have withdrawn about 96,000 tons of salts equivalent to around 40,000 tons of $K_2O$ from stocks accumulated in 1937. Domestic producers supplied about 52 percent of the 467,000 tons of potash ($K_2O$) that moved from primary sources into domestic channels for consumption.

Domestic output rose 11 percent in 1938 to 534,945 short tons of salts equivalent to 316,951 tons of $K_2O$ from 486,090 tons equivalent to 284,497 tons of $K_2O$ in 1937. The average grade was 59.2 percent $K_2O$ in 1938 compared with 58.5 percent in 1937. Production exceeded sales by more than 30,000 tons of potash, and producers' stocks were correspondingly increased, the year-end carry-over rising to 87,000 tons of $K_2O$.

Producers sales expanded 7 percent to 286,437 tons of potash in 1938 from 266,938 in 1937, notwithstanding a drop of around 10,000 tons in domestic consumption, and the value at the plant increased to $9,748,290 compared with $9,019,534 in 1937. The 1938 average value of $19.57 per ton was 25 cents more than the 1937 average.

Estimates of consumption based on sales reported for 1938 are not directly comparable with the corresponding figures for 1937 because final delivery dates on orders placed with the principal producers and importers during the discount periods were advanced in 1938 to December 31, whereas 1937 contracts called for delivery in approximately equal monthly installments to January 31, 1938. Hence, 1938 sales and consumption figures might be considered to represent 13 months' business if calculated on the same basis as those for 1937. If the custom of previous years had been followed 20,000 to 30,000 tons of potash might have been delivered in January 1939 on 1938 contracts and would then have been reported as 1939 sales. Therefore, for the purpose of comparing the use of potash in agriculture and industry in 1938 with that in 1937, the 1938 consumption probably

Digitized by Google

should be estimated at around 440,000 tons, although producers and importers actually delivered 467,000 tons to buyers for manufacture into fertilizer and other minor uses. The decline in fertilizer sales reported by the National Fertilizer Association—from 8,195,000 tons in 1937 to 7,504,000 tons in 1938—would indicate a shrinkage of 35,000 to 40,000 tons in the amount of potash consumed on American farms.

The effect of completing deliveries on 1938 contracts within the calendar year is evident also in the 40,000-ton drop in deliveries reported by the American Potash Institute for the first quarter of 1939 compared with the corresponding period of 1938.

Output of the American Potash & Chemical Corporation at Trona, Calif., and that of the United States Potash Co. and of the Potash Co. of America near Carlsbad, N. Mex., comprised over 98 percent of the total production. The California company extracts potash and other salts from the brine of Searles Lake, and at the two New Mexico operations sylvinite is mined from a depth of about 1,000 feet and refined at nearby plants. Small shipments of crude minerals from various operations in Utah and Wyoming contributed unimportant amounts to the total, and a few thousand tons of potash-bearing material was recovered from distillery waste and cement flue dust. Bonneville, Ltd., a Salt Lake corporation operating near Wendover, Utah, began in July small but steady shipments of muriate extracted from the brines of Salduro marsh, by methods recently developed.

Imports were mainly of German and French origin, although increased shipments were received from Palestine and Spain, and importation of crude saltpeter from Chile continued. It is doubtful whether the Spanish mines were worked at all during 1938, and shipments by the Loyalist Government probably came from stocks at Barcelona. Following the victory of the Nationalist forces under General Franco the return of the potash mines to their owners is anticipated, and production and export doubtless will be resumed under the old arrangement with the International Cartel.

The decrease in exports from approximately 62,000 tons of potash in 1937 to 51,800 tons in 1938 was explained by the decline in shipments to Japan that was only partly offset by larger sales to Belgium and Norway. About 16,000 tons of salts containing nearly 10,000 tons of potash represented resales by customers of producers and importers. The economic situation in Japan may result in further curtailment of sales to that country, which in 1938 maintained its position as America's best customer for potash in spite of reduced imports.

The Potash Export Association, Inc., organized by American Potash & Chemical Corporation, United States Potash Co., and Potash Co. of America, to handle their export sales, filed a statement in December with the Federal Trade Commission, under the Webb-Pomerene Export Trade Act of 1918, setting forth its place of business, officers, and members and declaring its purpose to engage in exporting potash salts. This act exempts from antitrust laws associations entered into for the sole purpose of engaging in export trade "provided such association, agreement, or act is not in restraint of trade within the United States, and is not in restraint of the export trade of any domestic competitor of such association."

Salient statistics of the domestic potash industry for 1937 and 1938 are summarized in the following table:

*Salient statistics of the potash (crude and refined potash materials) industry in the United States, 1937–38*

| | 1937 | 1938 |
|---|---|---|
| Production: | | |
| Potassium salts, short tons | 486,090 | 534,945 |
| Approximate equivalent, $K_2O$, do | 284,497 | 316,951 |
| Sales: | | |
| Potassium salts, do | 466,933 | 498,189 |
| Approximate equivalent, $K_2O$, do | 266,938 | 286,437 |
| Value at plant | $9,019,534 | $9,748,290 |
| Average per ton | $19.32 | $19.57 |
| Imports: | | |
| Crude and refined, short tons | 810,529 | 450,387 |
| Approximate equivalent, $K_2O$, do | 351,445 | 193,609 |
| Value | $19,733,076 | $13,512,110 |
| Exports: | | |
| Fertilizer materials, short tons | 103,031 | 84,137 |
| Approximate equivalent, $K_2O$, do | 61,000 | 50,500 |
| Value | $3,278,895 | $2,599,772 |
| Other, short tons | 2,094 | 2,616 |
| Approximate equivalent, $K_2O$, do | 1,000 | 1,300 |
| Value | $484,450 | $485,672 |

## PRICES

Except for shortening to December 31 the delivery period on orders subject to the published discounts, schedules of prices issued by producers and importers in May 1938 were virtually identical with those of the year before. Muriate was quoted at 53½ cents per unit of $K_2O$, 30-percent manure salts at 58½ cents, 20-percent kainite at $12.75 per ton in bulk, sulfate of potash (90-percent $K_2SO_4$) at $38 per ton in bags, and sulfate of potash-magnesia (48-percent $K_2SO_4$) at $25.75 per ton in bags. As usual, prices were guaranteed against reduction. A 12-percent discount was offered on orders placed before July 1 for delivery in approximately equal monthly installments to December 31 and 5 percent on orders placed from July 1 to September 30 for delivery to December 31. On orders placed after September 30 for delivery during the remainder of the fertilizer year to May 31, 1939, prices were net.

The following table shows the monthly average prices prevailing during 1938 in accordance with published schedules:

*Average prices per short ton of potash salts in 1938, by months*

| Month | Muriate of potash, 50-percent $K_2O$, in bulk | Sulfate of potash, 90-percent $K_2SO_4$, in bags | Sulfate of potash-magnesia, 48-percent $K_2SO_4$, in bags | Manure salts, 30-percent $K_2O$, in bulk | Kainite, 20-percent $K_2O$, in bulk |
|---|---|---|---|---|---|
| January to May | $26.75 | $38.00 | $25.75 | $17.55 | $12.75 |
| June | 23.54 | 33.44 | 22.66 | 15.44 | 11.22 |
| July to September | 25.41 | 36.10 | 24.46 | 16.67 | 12.11 |
| October to December | 26.75 | 38.00 | 25.75 | 17.55 | 12.75 |

## CONSUMPTION AND USES

Approximately 467,000 tons of potash were sold in 1938 by producers and importers for the manufacture of mixed fertilizers and for chemical and other industrial uses in the United States. About 94 percent of the total was destined for use in agriculture. From information available to the Bureau of Mines no estimate can be made of ultimate consumption by application to the soil or utilization in industry.

The American Potash Institute reports that deliveries by member companies in the United States and its possessions in 1938 totaled 439,561 tons of potash and that 40,843 tons were exported. Importations and sales of all other primary suppliers amounted to 38,938 tons, indicating a total movement of potash of 519,342 tons from primary sources to buyers. Deducting exports of 51,800 tons leaves 467,542 tons sold for consumption in the United States. Apparent consumption calculated by subtracting exports (51,800 tons) from the sum of domestic sales (286,437 tons) and imports (193,609) was only 428,246 tons. The difference of 39,296 tons appears to have been withdrawn from previously accumulated importers' stocks. The basis of this estimate is shown in the following tabulation of deliveries by member companies of the American Potash Institute, sales by nonmember producers, entries by nonmember importers, and total exports.

*Sales of primary potash for consumption and export in 1938, in short tons*

| | Bulk salts | Equivalent $K_2O$ |
|---|---|---|
| Deliveries by member companies, as reported by American Potash Institute: | | |
| In United States and possessions: | | |
| Agricultural | 821,406 | 423,977 |
| Chemical | 25,591 | 15,584 |
| For export | 68,116 | 40,843 |
| | 915,113 | 480,404 |
| Imports not included above plus sales of nonmember producers | 129,872 | 38,938 |
| | 1,044,985 | 519,342 |
| Total exports | 86,753 | 51,800 |
| Actual sales for consumption in United States | 958,232 | 467,542 |
| Apparent consumption | 861,823 | 428,246 |
| Apparent withdrawals from importers' stocks | 96,409 | 39,296 |

## PRODUCTION AND SALES

The tonnage of potash in marketable salts produced by mines and plants in the United States continued the upward trend begun in 1922 from the low level of postwar liquidation. The increase of 11 percent—from 284,497 tons in 1937 to 316,951 in 1938—was only slightly less than the 13-percent gain made in 1937. Sales, however, increased only 7 percent, and about 32,000 tons were added to stocks. Value at the plant of salts sold increased $728,756 (8 percent) to $9,748,290. The average grade of salts produced was 59.2 percent $K_2O$, an increase of 0.7 percent from the 1937 average. About 52 percent of the home market was supplied by producers, and about 8.5 percent of their sales were for export.

One new source of potential importance was exploited during the year by Bonneville, Ltd., which began in July small shipments of high-

Digitized by Google

grade muriate recovered from brines of the Salduro marsh at Wendover, Utah. Nearly 900,000 tons of crude salts averaging about 25 percent $K_2O$ were mined from the bedded saline deposits in New Mexico.

Production and sales of marketable potassium salts and stocks in the hands of producers for the last 5 years are summarized in the following table. Only the final weight of marketable salts after refining or mixing is shown. For similar data from the beginning of the potash-producing industry in 1915 to 1934 see the chapter on Potash in the Minerals Yearbook 1935. Data by States and sources cannot be given without disclosing individual reports.

*Potassium salts produced, sold, and in producers' stocks in the United States, 1934–38*

| Year | Production | | | Sales | | | | Producers' stocks | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | Operators | Potassium salts (short tons) | Equivalent as potash ($K_2O$) (short tons) | Operators | Potassium salts (short tons) | Equivalent as potash ($K_2O$) (short tons) | Value f. o. b. plant | Operators | Potassium salts (short tons) | Equivalent as potash ($K_2O$) (short tons) |
| 1934 | 8 | 275,732 | 144,342 | 8 | 224,875 | 114,122 | $2,813,218 | 4 | 95,844 | 50,066 |
| 1935 | 10 | 357,974 | 192,793 | 10 | 406,922 | 224,721 | 4,993,481 | 6 | 47,710 | 18,060 |
| 1936 | 7 | 431,470 | 247,340 | 7 | 396,690 | 222,810 | 6,969,190 | 5 | 73,139 | 34,000 |
| 1937 | 7 | 486,090 | 284,497 | 7 | 466,933 | 266,938 | 9,019,534 | 5 | 105,900 | 55,620 |
| 1938 | 9 | 534,945 | 316,951 | 9 | 498,189 | 286,437 | 9,748,290 | 6 | 158,540 | 87,440 |

## GOVERNMENT ACTIVITIES

The Senate investigation of the potash industry, started in 1936 under authority of Senate Resolution 274, 74th Congress, 2d Session and pursued spasmodically during 1937, was virtually recessed during 1938 following a 2-year extension, authorized May 18, 1938, of the time allowed the committee for completing the investigation and reporting to the Senate. The inquiry is in charge of a subcommittee of the Senate Committee on Public Lands and Surveys. It was instituted to determine whether unfair or illegal practices were being employed in the exploitation of potash resources and the extent of foreign ownership or control of American potash companies. The fact that the investigation is languishing leads to the surmise that the industry was found to be functioning reasonably well in the public interest. The three important operations afford employment at high wages to about 1,800 men and have been developed, without benefit of tariff protection, in competition with low-cost foreign producers to a degree that insures independence of foreign supplies.

Potash Reserve No. 6, New Mexico No. 1, withdrawn from entry by Executive order of March 11, 1926, and Potash Reserve No. 7, New Mexico No. 2, withdrawn by Executive order of June 8, 1929, together comprise 9,282,160 acres and include all of Lea, Roosevelt, and Curry Counties and parts of Eddy, Chavez, and De Baca Counties in southeastern New Mexico. In these areas, insofar as title remains in the United States, potassium and sodium deposits are severed from the surface and reserved to the United States, subject to lease under the mineral leasing laws. All mining operations on public land mineral leases are supervised by the Geological Survey, which is likewise charged with land classification.

Digitized by Google

Several leases were issued during the year by the Secretary of the Interior, including three to the Union Potash & Chemical Corporation, whose applications had been pending for some time.

## REVIEW BY STATES

*California.*—Operations of the American Potash & Chemical Corporation at Trona, Calif., continued throughout the year. In addition to potash, borax, soda ash, and salt cake this company is now recovering lithium from the complex brine of Searles Lake in the form of sodium lithium phosphate containing about 22 percent lithia, which is sold to a company that supplies the trade with lithium salts for various uses. The rapid growth of air-conditioning, in which lithium chloride is used for dehumidifying the air, is fast creating a broader market for lithium salts.

*Maryland.*—Byproduct potash was produced by the North American Cement Corporation at Hagerstown and the United States Industrial Chemical Co. at Baltimore, the former from cement-kiln dust and the latter from distillery waste. These two companies annually supply a few thousand tons of material that is marketed as agricultural potash.

*New Mexico.*—Output of the two potash mines near Carlsbad in 1938 approached 900,000 tons of crude salts averaging about 25 percent $K_2O$—the largest mine production yet recorded. The United States Potash Co. and the Potash Co. of America are the only producers in the State. Most of their mine product is refined and sold in the form of high-purity muriate, although there is still a relatively small market for run-of-mine and mixed salts of lower analysis. First shipments from this area were made in 1931, and development since that time has been rapid.

The shaft of the Union Potash & Chemical Corporation was completed by the International Agricultural Corporation to a depth of 925 feet, and levels were opened at 787 feet and 907 feet, under an option agreement understood to involve a controlling interest in the property. Additional drilling is now in progress to explore further the three leases, aggregating 7,680 acres, that constitute the present holdings. Numerous potash-bearing beds were cut by the shaft, the more important being mixtures of langbeinite and sylvite. In this respect the deposit appears to differ from others in the district now being mined, where langbeinite is not found in important quantities.

*Utah.*—The early potash investigations of the Geological Survey, beginning in 1911, included a study of the brines of the Salduro marsh in western Utah, which were found to contain varying amounts of potassium chloride associated with sodium and magnesium salts. Under the stimulus of high prices created by the potash shortage during the World War plants were built to recover potash from these brines, and several thousand tons of fairly high-grade muriate were produced. However, costs were high, and when imports were resumed and prices returned to normal after the war the plants were forced to close. No potash from this source was reported after 1921. In 1938 operations in this area were resumed on a small scale by Bonneville, Ltd., following extended experimentation. The plant of this company is near Wendover, close to the Nevada line. The first shipment was made in July, and shipments continued throughout the rest of the year. Crude salts are recovered from the brine by solar evaporation and refined to produce high-grade muriate.

## FOREIGN TRADE [1]

*Imports.*—Potash imports dropped abruptly in 1938 to 193,609 short tons, a decrease of 157,836 tons (45 percent) from the all-time peak of 351,445 tons established in 1937. Fertilizer salts contained 93 percent of the potash imported, and salts imported for use in the chemical industries the remaining 7 percent.

The quantity, average grade, and total declared value of the various potash salts imported in 1937 and 1938, the countries from which shipments were made, and the approximate $K_2O$ equivalent of imports for the past 5 years are shown in the following tables.

*Potash materials imported for consumption in the United States, 1937–38*

| Material | Approximate equivalent as potash ($K_2O$) (percent) | 1937 | | | | 1938 | | | |

*Exports.*—Shipments of fertilizer salts to Japan, the largest buyer of American potash, were 28,000 tons less in 1938 than in 1937; and although exports to Canada and Europe expanded, the total was 18 percent below the 1937 figure. About 80 percent represented direct sales by producers and 10 percent resales from consumers' or speculators' stocks. Exports of chemical salts were slightly higher in 1938 than in 1937.

## WORLD PRODUCTION

The output of potash in marketable salts increased in all the leading producing countries except Spain in 1938. As already stated, shipments from Spain by the Loyalist Government are considered to have been drawn from stocks at Barcelona and not to represent new production. Although no authentic information is available it is believed that the Spanish mines, which were in Loyalist territory throughout the war, were not operated during 1938. Assuming an increase of 10,000 tons in Soviet output, world production rose 10 percent to a new high of 3,100,000 metric tons of $K_2O$ in crude and refined salts of marketable grade. The following table is based on estimates and available information from official and unofficial sources.

## FOREIGN DEVELOPMENTS

*British India.*—The American trade commissioner at Calcutta reports that the domestic production of potassium nitrate in British India was affected adversely by unfavorable weather and floods. Higher prices demanded caused substitution by consumers of synthetic nitrates, and exports fell to 7,387 tons from 8,357 tons in 1937.

*France.*—Output of crude salts from the French mines established a new record of 3,375,000 tons in 1938 that exceeded by 241,000 tons the previous record made in 1930. Sales also were greater than ever before, but because of the increased home demand producers were unable to supply their full export quota established by the International Cartel. Domestic prices have not been changed for a number of years, while costs have advanced because of social legislation and a generally rising commodity price level until there is little profit in domestic sales. The obligation to satisfy home demands before selling for export has prevented producers from taking full advantage of exchange conditions prevailing in other markets owing to depreciation of the franc. Sales in France are reported to have exceeded exports by about 18 percent. The potash mines are subject to Government control through the common sales agency established by the law of January 23, 1937, which has sole right of sale both at home and for export.

*Germany.*—More than 15,000,000 tons of crude potash salts averaging around 13.8 percent $K_2O$ were mined by German producers in 1938, the greatest mine output ever recorded in the history of the industry. The percentage of mine output sold as mined or mixed with refined salts to produce intermediate grades has been decreasing in recent years in line with the trend toward high-analysis fertilizers. From 85 to 90 percent is processed to produce muriate, sulfate, and other of the higher-grade salts to which market demand has shifted. In 1938 the mine output of approximately 15,000,000 tons was converted into 5,190,000 tons of salts of all marketable grades averaging 35.8 percent potash, equivalent to 1,860,000 tons of $K_2O$.

Mine output and marketable salts produced from 1932 to 1938 are stated in the following table.

*Production of potash salts in Germany, 1932–38*

[Thousands of metric tons]

| Year | Salts mined | | Marketable salts produced | |
|---|---|---|---|---|
| | Gross weight | Equivalent $K_2O$ | Gross weight | Equivalent $K_2O$ |
| 1932 | 6,416 | 871 | 2,801 | 787 |
| 1933 | 7,363 | 1,026 | 3,131 | 906 |
| 1934 | 9,617 | 1,329 | 4,175 | 1,179 |
| 1935 | 11,673 | 1,597 | 4,712 | 1,396 |
| 1936 | 11,765 | 1,623 | 4,734 | 1,441 |
| 1937 | 14,460 | 1,968 | 5,122 | 1,690 |
| 1938 | [1] 15,300 | [1] 2,114 | 5,190 | 1,860 |

[1] Estimated.

Digitized by Google

Under Government pressure to increase crop production and measures to cheapen the cost of fertilizers, consumption of potash by German farmers has expanded rapidly in recent years. Domestic sales rose from 620,000 metric tons of $K_2O$ in the fertilizer year 1932–33 to 1,156,000 tons in the fertilizer year 1937–38, an increase of 86 percent in 5 years. However, Government-controlled prices have been maintained at an unprofitable level, and producers look to export business and expansion of byproduct manufacture to produce earnings for their stockholders. Notwithstanding rising sales, net profits, and dividend disbursements of the leading companies have declined steadily.

Exports in 1938 were sharply reduced from the 1937 level, owing mainly to smaller sales in two of the leading markets, the United States and Japan. Exports of raw potash salts declined only 10.5 percent to 698,546 metric tons, but exports of processed salts dropped 47 percent to 395,325 tons. The average value, in marks per metric ton, of raw salts exported rose from 39.38 in 1937 to 41.71 in 1938, but that of processed salts decreased from 68.87 in 1937 to 64.30 in 1938.

Increased demand for potash and more particularly for the processed salts has necessitated large expenditures in plant expansion and facilities for storing and handling the finished products. Wintershall A. G., the dominant factor in the potash industry that directly controlls 42 percent of the output, reports that in 1937 an investment of 31,000,000 marks was required for plant enlargement, purchase of new machinery, and plant improvements compared with 14,190,000 marks in 1936. Vice Consul G. M. Gerrity, attached to the American consulate general at Frankfort on the Main, states that the immense gains in national production of potash in recent times have resulted to only a moderate degree in increased earnings of German potash companies owing to the combined factor of heavy investments required for new plant equipment, uncertainties in the international trade and, since the spring of 1937, the Government's drastic reductions by around 25 percent of the fixed domestic prices of potash fertilizer. Thus, in spite of its heavily increased business, the Wintershall A. G. increased its net earnings only moderately in 1937—to 6,027,000 marks from 5,747,000 in 1936 and 5,710,000 marks in 1935. The company continued the 5-percent dividend upon its 125,000,000 marks of common stock, or the same rate in effect for the 2 preceding years.

The writer is indebted to American Consul Sydney B. Redecker and American Vice Consul G. M. Gerrity for general information and factual data on the German potash industry.

*Japan.*—According to the American commercial attaché at Tokyo, Japanese producers of potassium chlorate contend that changed conditions in China have made the international sales agreement of March 30, 1937, with European producers unworkable. The agreement, which allocated sales territories and export quotas, allotted all of Japan and Manchuria and 55 percent of the Chinese market to Japanese producers. Plans are being pushed to utilize bittern and sea water as the basis of a chemical and metallurgical industry. The production of metallic magnesium, aluminum, potassium chloride,

Digitized by Google

sulfate and bromide, and ammonium sulfate is contemplated. The Japan Industrial Salt Co., Kobe Steel Manufacturing Co., and Meiji Mining Co. are interested in these projects.

*Poland.*—Mine production of crude potash salts in 1938 increased about 9 percent to 567,111 metric tons averaging 19 percent $K_2O$ equivalent to 108,380 tons of potash from 521,483 tons averaging 19 percent $K_2O$ equivalent to 99,940 tons of potash in 1937. Potash in marketable salts produced by refining and mixing the salts mined was reported to be 72,139 metric tons of $K_2O$ in 1938 compared with 62,489 tons in 1937. Stimulated by a price cut of 9 percent, sales of potash ($K_2O$) rose to 71,412 metric tons in 1938 from 64,605 tons in 1937. A slight reduction in Poland's export quota by the International Cartel was reported to have caused the decrease in exports of commercial potash salts from 84,803 metric tons in 1937 to 74,570 in 1938.

# MICA

By Paul M. Tyler and K. G. Warner

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1343 | Prices | 1349 |
| Salient statistics | 1344 | Foreign trade | 1349 |
| Domestic production | 1345 | Imports | 1349 |
| Sheet mica | 1345 | Exports | 1351 |
| Scrap mica | 1345 | World production | 1352 |
| Ground mica | 1346 | Subvarieties of muscovite | 1353 |
| Consumption and stocks of splittings | 1348 | Possible substitutes for mica | 1353 |

World prices of mica were well-maintained in 1938 by the active foreign demand that continued almost unabated, especially in Europe; but in the United States, owing to curtailed consumption and the large stocks held by manufacturers, demand receded to depression levels. In comparison with 1937—a remarkably good year in almost every branch of the mica-manufacturing industries—1938 leaves a drab record. Domestic production of uncut mica decreased 45 percent in 1938 and of larger sheet sizes over 55 percent from the relatively high levels of the preceding year. The total yield of punch and sheet mica from American mines was less than in any but the worst years of the last three decades, amounting to only 939,507 pounds worth $139,333 compared with 1,694,538 pounds valued at $285,244 in 1937.

Domestic needs for the better qualities of mica, however, are supplied principally by imports, and the curtailed demand is shown further by the sharp reduction in receipts of foreign mica of all important kinds. Imports of sheet and block mica aggregated only 391,125 pounds with a nominal foreign market valuation of $113,403 compared with 1,004,950 pounds and $296,235 in 1937; the decrease in this category was more than 60 percent. In respect to splittings (the principal import item) the decrease was almost 75 percent, from 7,932,867 pounds valued at $1,598,969 in 1937 to 1,979,162 pounds valued at $445,323 in 1938. Domestic consumption of splittings reported to the Bureau of Mines decreased over 60 percent, and the large stocks carried over from 1937 were increased further.

Running counter to the general trend of the industry was the prosperity of the mica-grinding portion. Shipments of ground mica almost equaled the 1937 record in quantity and exceeded it by 10 percent in value. Increased demands for paint, wallpaper, and other miscellaneous uses more than offset a 13-percent reduction in the quantities used in roll roofing, which, however, took 70 percent of the total tonnage. Despite the activity of mica-grinding mills, their purchases of scrap declined in 1938, and since European buying is a minor factor in this market, prices of newly mined waste mica were greatly reduced.

Digitized by Google

The total production of uncut sheet mica and scrap in the United States was 20,727 short tons valued at $395,715 in 1938 compared with 26,043 short tons valued at $639,981 in 1937 and 21,615 tons valued at $464,473 in 1936. Imports totaled 5,761 tons, nominally valued at $664,419 on a foreign market basis; in 1937 they aggregated 11,339 tons with a declared valuation of $2,067,599 and in 1936, 6,678 tons valued at $1,205,568. The foregoing figures for domestic and imported mica, respectively, make it appear that almost four times as much mica was produced in the United States as was imported in 1938. This is true in respect to total tonnage but actually the United States seldom produces as much as one-third of its requirements of sheet mica (larger than 1½ by 2 inches) and only a negligible amount of its requirements of splittings. The bulk of the domestic output is scrap, ground mica schist, and byproduct mica, although American mines also produce almost enough punch and circle mica—used for making washers and small radio stampings—to meet domestic needs.

For many years mica has been considered one of the few materials for which no acceptable substitute was available in many of its principal uses. Recent laboratory research indicates that a product (Alsifilm) made from bentonite may compete successfully with mica in the important electrical field, if it can be produced commercially. Another challenge to sheet mica and mica splittings may come from properly processed ground mica, though this development seems to be less far advanced than Alsifilm, which may be marketed on a semicommercial scale in 1939.

## DOMESTIC PRODUCTION

*Sheet mica.*—Mica seems to have been the first mineral mined in North America. Thousands of tons of debris on the dumps testify to the extent of the ancient workings operated by western North Carolina aborigines. The mica ornaments left by Ohio Valley mound builders likewise confirm the importance of this mineral to primitive peoples, who prized it chiefly as a decoration and perhaps as a medicine and a charm.

The first mica mine to be operated on a commercial scale in this country was probably the Ruggles, in New Hampshire, which was opened in 1803 to provide "isinglass" for stove windows. It is said also to have furnished sheets for gunboat windows, because gunfire would shatter ordinary glass. As the demand for mica developed very slowly early production in New Hampshire was only sporadic; mining on a relatively stable basis was started in 1868 in North Carolina. Since that date the latter State ordinarily has been the leading producer, occasionally alternating with New Hampshire and possibly yielding first rank to South Dakota for a year or two.

Production statistics on mica have been published annually since 1880, when the output of American mines was 81,669 pounds valued at $127,825. After rising to 147,410 pounds worth $368,525 in 1884 it dwindled rapidly owing to the competition of Indian mica, which was imported first in 1885. The rapid growth of the electrical industry during the 1890's so increased the demand for sheet mica that in 1898 domestic output once more rose above 100,000 pounds and at the turn of the century jumped to 456,283 pounds valued, however, at only $92,758. By 1906 the output had grown to 1,423,100 pounds with a value of $252,248. In 1910 it attained a peak of 2,476,190 pounds—but this was mostly small mica, as the value was only $283,832 whereas the 1,700,677 pounds produced in 1913 was worth $353,517.

In the earlier years some mica miners operated cutting plants; and the value of their finished products, such as stove mica and other more or less standard sizes, was included in the production statistics. Since 1920, however, the production as officially reported comprises uncut sheet mica alone. Beginning with 1920 also, separate figures have been compiled for uncut "punch" and uncut sheet larger than punch. "Punch mica" is a domestic term not generally used abroad and refers to crystals of book or block mica, usually thumb-trimmed, as opposed to knife- or shear-trimmed, but not large enough to furnish sheets more than about 1½ inches in diameter. Included with punch mica is circle mica, which is somewhat larger, yielding circles up to 2 inches in diameter.

*Scrap mica.*—The United States probably consumes 90 percent of the scrap and waste mica used. It is the only country that has a large demand for ground mica or that has had long and successful experience in grinding mica, which is one of the most difficult minerals to grind without destroying certain of its useful properties.

Separate statistics covering domestic mine production of scrap mica have been available continuously since 1893, when an output of 156 tons was recorded. In 1900 the output soared to 5,497 tons valued at $55,202, but this was abnormal and the annual average for the 5-year pre-war period, 1909–1913, was 4,043 tons valued at $55,296. The annual average for the predepression period, 1925–29, was 7,406

Digitized by Google

tons valued at $134,128, thus showing an increase of 85 percent in less than two decades. The actual rise was even greater, because a substantial recovery of mica from clay washing as well as production from schists had been developed. These items, amounting to 6,667 short tons valued at $111,345, were included in the statistics for 1935 when the total production of scrap, ground mica schist, and byproduct mica advanced to 18,852 tons valued at $243,951. Later figures are shown in the accompanying table.

*Mica sold or used by producers in the United States, 1925–38*

| Year | Sheet mica | | | | | | Scrap mica | | Total | |
|---|---|---|---|---|---|---|---|---|---|---|

[2] Includes mica recovered from kaolin and schists as follows: 1937, 5,115 short tons valued at $90,994; 1938, 3,971 tons, $64,542.
[3] 1937: Arizona, California, Colorado, Georgia, Maine, New Mexico, South Carolina, South Dakota, Utah, and Virginia. 1938: Arizona, California, Colorado, Georgia, Maine, New Mexico, South Carolina, South Dakota, Virginia, and Wyoming.
[4] Includes mica recovered from kaolin and schists as follows: 1937, 5,421 short tons valued at $58,937; 1938, 2,579 tons, $22,060.
[5] Connecticut included with New Hampshire.

*Ground mica.*—The earlier data for ground mica are as incomplete as those for scrap mica, in that they likewise fail to include byproduct mica and ground schist mica. Reclaimed mica from clay washing competes with dry-ground mica in the important roofing market, but because it ordinarily does not have to be ground it was excluded from the statistics until 1930. Schist mica, which was produced in fairly large amounts as early as 1923 and to some extent even earlier, was excluded until 5 years later. Beginning with 1935, however, the Bureau of Mines has reported as "ground mica" all classes of material—including wet- and dry-ground muscovite, mica recovered from clay washing, byproduct mica from kyanite or other concentrating operations, and the product of milling schists (whether muscovite, sericite, biotite, or even chlorite schist). In addition to domestic raw material several grinding plants use foreign mica,

Digitized by Google

both imported mine scrap and factory scrap from the manufacture of products of imported sheet mica and splittings.

The true growth of the ground-mica industry is portrayed faithfully in the official production figures, even though they are slightly distorted for a decade or two by the aforementioned statistical details. After fluctuating for many years between 3,000 and 4,000 short tons the annual output about 1925 began to rise rapidly, reaching 18,323 tons in 1935 and continuing upward to a new all-time record of 27,245 tons valued at $839,812 in 1937.

*Ground mica sold by producers in the United States, 1925–38, by methods of grinding*

| Year | Dry-ground | | Wet-ground | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1925–29 (average) | 2,436 | $89,624 | 2,821 | $301,122 | 5,257 | $390,746 |
| 1930–34 (average) | 5,967 | 155,471 | 2,517 | 224,838 | 8,484 | 380,309 |

[1] Includes mica from kaolin and schist.

Especially notable in 1938 were the substantial increases in sales of wet-ground mica for wallpaper and for paint. Although the paint industry even yet takes only 6 percent of the total sales its consumption was more than half again as large in 1938 as in 1937 and many times larger than in any year before 1936. There was an even more remarkable increase in shipments for miscellaneous uses. This category includes a considerable tonnage sold for an undisclosed "new use," but consumption for several other uses also rose sharply. These increases almost counterbalanced the 13-percent decrease in sales for roll roofing, still the principal use, and contributed to the 10-percent increase in the value of the total output.

*Ground mica sold to various industries in the United States, 1937–38*

| Industry | 1937 | | | 1938 | | |
|---|---|---|---|---|---|---|
| | Quantity | | Value | Quantity | | Value |

[1] Includes mica from kaolin and schist.
[2] Includes mica used for molded electric insulation, house insulation, Christmas-tree snow, manufacture of axle greases and oil, annealing, pipe-line enamel, plastic specialties, textiles, pipe and boiler covering, coating levee mattresses, and other purposes.

Digitized by Google

Mica filler is employed principally to increase the dielectric properties of molded plastics, especially molded phenolic resins for electrical uses; it is also used in rubber. The potential use of ground mica is enormous. It may be used advantageously to the extent of 10 percent of the total pigment in paints and universal adoption by the paint industry would afford a market for as much as 100,000 tons annually. A possible competitor in this field is a new pigment developed by the Universal Insulation Co., Chicago, Ill., intermediate in composition between vermiculite and mica.

## CONSUMPTION AND STOCKS OF SPLITTINGS

After expanding steadily for 5 years to an all-time record in 1937 the consumption of mica splittings contracted sharply in 1938 to 1,667,806 pounds with a value of only $612,465 compared with 4,347,435 pounds worth $1,257,645 in the preceding year. The consumption in 1938 was the smallest since 1933, but stocks in consumers' hands increased by 7 percent above the abnormally heavy inventories carried over from 1937 and at the close of the year were three times as large as at the end of 1936.

Indian muscovite splittings still constitute more than 85 percent of the total consumed; however, Madagascar splittings now represent over 10 percent and have become more than twice as important as those from Canada, which enjoyed a monopoly of the amber-mica business until about 1919. Occasional batches of splittings are reported as produced by domestic mines and trimming or sorting plants, and small amounts are made in the United States from imported mica, but the aggregate quantity of American-made splittings is virtually negligible.

*Consumption and stocks of mica splittings in the United States, 1934–38, by sources, as reported by the consumers*

| Year | India | | Canada | | Madagascar | | Total | |

## PRICES

Mica is marketed as (1) cut or uncut block, (2) sheet, (3) splittings, and (4) wet- or dry-ground, but the value depends on the size of flat sheets into which it can be split and on whether it is clear or stained. The complexity of grading and classifying sheet mica is indicated by the fact that at least 100 distinct products can be classed as unmanufactured mica. Not only do the sheets vary enormously in size, but for each size there are at least six different qualities ranging from clear to black-stained. To attempt to report prices of all these different grades (sizes) and classes (qualities) year after year would be an endless task and one that would reveal little beyond the general trend toward relatively higher prices for smaller sizes.

Trade-journal quotations for domestic mica in 1938 were about the same as in 1937 and did not differ greatly from those reported for the latter part of 1936 and tabulated on page 1405 of Minerals Yearbook 1937. Actual prices paid for specified sizes in 1938 as reported to the Bureau of Mines by producers are shown in the following table.

*Average value per pound of domestic uncut sheet mica sold in 1938*

| Size | Clear | Stained or spotted | Size | Clear | Stained or spotted |
|---|---|---|---|---|---|
| Punch or washer | $0.056 | $0.055 | 3 by 4 inches | $1.329 | $0.870 |
| Circle | .103 | .151 | 3 by 5 inches | 1.752 | 1.099 |
| 1½ by 2 inches | .262 | .199 | 4 by 6 inches | 2.758 | 1.353 |
| 2 by 2 inches | .510 | .243 | 6 by 8 inches | 4.127 | 1.495 |
| 2 by 3 inches | .871 | .451 | 8 by 10 inches | 8.394 | 1.297 |
| 3 by 3 inches | 1.103 | .630 | 10 by 12 inches | 9.429 | ---------- |

## FOREIGN TRADE [1]

*Imports.*—In 1938 the imports of mica aggregated only 5,761 short tons, compared with 11,339 tons in 1937. Moreover, whereas the quantity imported was roughly one-half the total for the preceding year, the declared value in 1938 was less than one-third. Imports of scrap mica were not listed separately before June 18, 1930, but it is generally conceded that they were unimportant until the late 1920's. They increased to 3,893 short tons in 1936 and to 6,723 tons in 1937. In 1938 they dropped to 4,450 tons; but as the imports of mica other than scrap dropped far more, the proportion of scrap to total imports was greater in that year than ever before. The chief value of the imports is in splittings, imports of which were reduced sharply because of the great curtailment in consumption and the large stocks already on hand. For many years the trend has been to use larger proportions of the lower-priced kinds of mica, and in 1938 the shrinkage in imports affected most of the higher-priced grades. Less unmanufactured sheet or block mica was imported in 1938 than in any year since 1932.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

[1] Includes 5,639 pounds valued at $3,757 of "All manufactures of which mica is the component material of chief value," no imports of which are shown in 1938.

As usual, British India was the principal source of imported scrap mica as well as of splittings and the more costly kinds of unmanufactured mica. Madagascar has become the second leading source of splittings, while Canada has fallen to a poor third. In 1938 the Union of South Africa displaced Canada from second place, even as a supplier of scrap. South American countries are increasingly important sources of block mica.

Under the reciprocal trade agreement with Canada, effective January 1, 1939, the duty on imported phlogopite mica waste and scrap valued at not more than 5 cents per pound was reduced from 25 percent ad valorem to 15 percent, and the duty on punch-size phlogopite (untrimmed) was lowered from 15 percent to 10 percent. Imports from Canada are amber mica or phlogopite, whereas those from all but one other country are muscovite. Madagascar, the only other producer of phlogopite, has never shipped scrap mica. The Canadian agreement also cut the duty on ground mica from 20 to 15 percent ad valorem. In discussing this latter change the Tariff Commission notes that although small quantities of mica are ground in other countries (Great Britain, Germany, France, and Japan), their combined output totals only a few hundred tons annually and the United States is on an export basis. Duties on other kinds of mica remain the same as in the original tariff act of 1930.

*Exports.*—Separate statistics of exports of ground mica became available for the first time in 1937, when they amounted to 1,532 tons, probably a record. The 1938 exports of 1,394 tons (worth $103,651) compare favorably with estimated foreign sales during the 1925–29 period and undoubtedly are greater than those for most years. The decline from the 1937 peak was due mainly to decreased shipments to Canada; shipments to United Kingdom, the largest buyer, increased slightly. Exports of unmanufactured mica increased by 139 tons but are unimportant. The shipments of manufactures other than ground mica, totaling 50,445 pounds valued at $75,379 in 1938, compare with 98,026 pounds and a value of $104,792 in the preceding year. This classification comprises principally repairs and replacements for American-made machinery and electrical apparatus.

## SUBVARIETIES OF MUSCOVITE

Volk,[2] after studying the optical and chemical properties of 22 samples of muscovite from all over the world, recommends three subdivisions: Potassium muscovite ($H_4K_2Al_6Si_6O_{24}$); phengite ($H_6K_2(Fe, Mg)_2Al_4Si_6O_{24}$); and ferric iron muscovite ($H_4K_2Fe_2'''Al_4Si_6O_{24}$). His formula for phengite differs from the old one, as it contains 1 more molecule of $H_2O$ and FeO or MgO and 1 less of $SiO_2$. In all three subvarieties the ratio of $R_2O$ ($K_2O$ and $Na_2O$) to $SiO_2$ is 1 to 6. Ferric iron muscovite, when present in the system, increases the refractive index.

## POSSIBLE SUBSTITUTES FOR MICA

The long quest for substitutes for mica in its principal electrical uses so far has been futile. No other substance combines many of mica's useful attributes. To escape dependence on large, unflawed sheets, which are rare in nature and hence costly, smaller sheets have been pasted or eyeletted together, and a fairly large industry has been established for making built-up mica from splittings. The built-up-mica industry, however, and the highly important fields that it serves have made the world more dependent than ever on British India for its mica. Not only has that country the largest mica mines, but it is one of the few countries where skilled labor is still cheap enough to permit splitting mica into thin films economically. Small books of mica that in the United States would be counted as waste fit only for grinding are converted laboriously into splittings in India. It is these splittings that are assembled and bonded—often with shellac, another Indian specialty—into built-up sheets or board, whether in the United States, England, Germany, France, or Japan.

Many years ago a large American company developed a substitute for built-up mica in commutator segments, and some of the electrical machinery in which it was used is still in satisfactory service. However, the material, which contained asbestos as an essential ingredient, tended to develop cracks after some time and so was abandoned. "Mycalex" is an important type of electrical insulation made by bonding coarsely ground mica with lead borate or soft glass; it competes with porcelain but not with sheet mica or mica board.

As noted in the introduction to this chapter, in 1938 there appeared a new material that promises to compete with sheet mica and perhaps displace mica board for a variety of electrical purposes. It may have an even better field of use to replace existing varieties of insulating tapes, including those made from high-grade pan-packed mica splittings. This material, called "Alsifilm," was developed in the laboratories of Dr. Ernst A. Hauser, Massachusetts Institute of Technology chemistry professor. It is processed from bentonite, and available information as to its properties and methods of production is summarized in the Minerals Yearbook 1939 chapter on Clays.

The other new development is the possible use of ground mica for certain applications of sheet mica or splittings. Japan is rumored to have made advances in this field, and an American inventor recently applied for patents and disclosed his plans to Bureau of Mines engineers.

# SALT

By A. T. Coons and F. E. Harris

## SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| Summary | 1355 | Distribution | 1360 |
| Salient statistics | 1355 | Value and prices | 1362 |
| Production | 1356 | Progress in technology and uses | 1362 |
| Evaporated salt | 1359 | Foreign trade | 1363 |
| Rock salt | 1359 | World production | 1365 |
| Salt content of brine | 1360 | | |
| Pressed blocks | 1360 | | |

After an all-time record of 9,241,564 short tons valued at $24,131,733 in 1937 the output of salt from domestic mines, wells, and ponds dropped 13 percent to 8,025,768 tons valued at $23,242,561 in 1938. According to reports of producers 2,429,100 tons of evaporated salt (valued at $15,566,439), 1,901,861 tons of rock salt (valued at $6,252,081), and 3,694,807 tons of salt in brine (valued at $1,424,041) were sold or used in 1938.

For a number of years salt in brine has comprised roughly one-half the salt production of the country. In 1937 it aggregated one-half of the total but in 1938 only 46 percent. The million-ton drop in total output of salt in 1938 was accounted for almost entirely by the 936,773-ton decrease in the production of salt in brine. The output of evaporated salt was only 150,452 tons less than in 1937, while that of rock salt dropped only 128,571 tons.

*Salient statistics of the salt industry in the United States, 1930–34 (average) and 1935–38*

| | 1930–34 (average) | 1935 | 1936 | 1937 | 1938 |

The chemical industries as a group were not affected as much as other industries by the 1932 depression, and they recovered faster. Heavy chemicals made from brine fared even better than other chemicals. Soda ash, for example, was aided by the growth in the glass industry, now the leading consumer of this material, and caustic soda shared in expansion of the rayon industry. The average monthly index of rayon deliveries rose from 74 in 1923 to 296 in 1929 and subsequently rose even more spectacularly to 816 in 1938. Meanwhile the Federal Reserve Board index for general business increased only from 102 in 1923 to 118 in 1929 and dropped to only 86 in 1938. Paper manufacture, another large consumer of soda ash and caustic soda, likewise has been much more active than other industries. For these reasons the output of salt in brine is still relatively high, even after the million-ton drop in 1938. In terms of index numbers based on percentages of the 1923–25 average output, it stood 50.5 points higher than the index of general industrial activity. The index for evaporated and rock salt, which depend on the relatively stable food industries, was 10 points higher than the general index. (See fig. 1.)

A report [1] on the marketing of salt was published early in 1939.

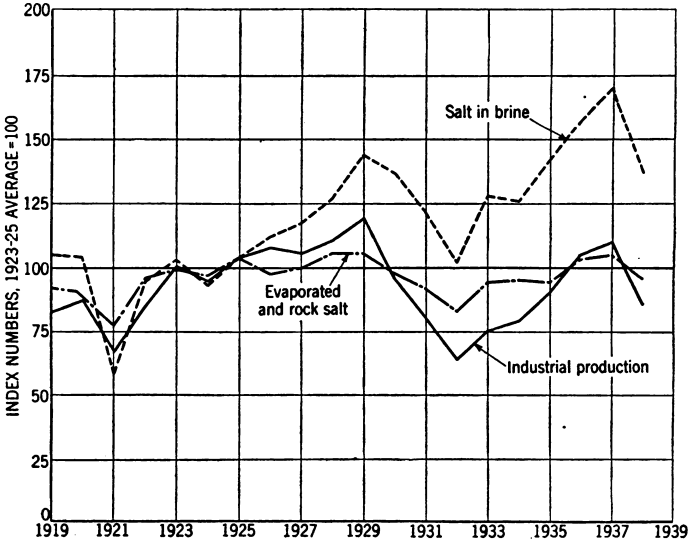

FIGURE 1.—Index of salt used in brine and evaporated and rock salt compared with Federal Reserve Board index of industrial activity, 1919–38.

## PRODUCTION

Notwithstanding a decrease in output, 79 plants (63 companies) reported operations in 1938 compared with 73 plants (59 companies) in 1937. Minerals Yearbook, 1936 (p. 920), listed producing companies in 1935, location of plants, and class of salt produced. Changes since then have been given in subsequent issues of Minerals Yearbook. Those in 1938 are as follows: Oliver Bros. Salt Co. and the American Salt Co. reopened and operated solar salt works at Mt. Eden, Alameda County, Calif.; the United States Vanadium Corporation, Uravan, Colo., produced evaporated salt for use in its own works at Bedrock,

[1] Harris, F. E., Marketing of Salt: Bureau of Mines, Inf. Circ. 7062, 1939, 56 pp.

Digitized by Google

Montrose County, Colo.; the Arenac Salt Co. was reported to have started operations near Sterling, Saginaw County, Mich.; plants along the Virgin River in Clark County, Nev., formerly producing small quantities of salt, have been submerged by the Boulder Dam project; the Union Potash & Chemical Co., Carlsbad, Eddy County, N. Mex., produced a small quantity of rock salt in connection with its development of potash deposits; Ezra S. Blackman, Freedom, Wood County, Okla., gathered a small quantity of solar salt from salt streams—a small refinery owned by him at this place was idle in 1938; the Crane Salt Co., Crane City, Crane County, Tex., started to produce solar salt from a salt lake on a small scale in 1938; and the Crystal White Salt Co., Salt Lake City, Utah, began construction of a plant at Grantsville, Tooele County, but no salt was marketed.

On the accompanying map (fig. 2) showing salt works and commercial deposits, prepared in collaboration with H. I. Smith, Geological Survey, no attempt has been made to include idle or abandoned plants. Only those plants producing in 1938 are shown. Because of the small scale of the map, surface deposits from which the salt is merely gathered, crushed, and sold without further treatment have been given the same designations as rock-salt mines and works where the salt occurs at depth. There are several such operations in California and near Redmond, Utah.

Several recent discoveries are shown on the map. A report [2] of the Louisiana Geological Survey refers to the 68 known salt domes of that State and cites the discovery (in 1937) of salt at Rodessa in northern Louisiana as an indication that a connection may exist between the North Louisiana and East Texas salt-dome areas. The North and South Louisiana salt-dome regions also may be connected, but the 60-mile-wide strip separating them is as yet relatively unexplored and is not mapped as salt bearing. New deposits have been discovered incident to drilling for oil in counties bordering the lower Gulf Coast region of Texas. In the Paradox Valley of Utah and western Colorado thick deposits of salt have been found, indicating an extensive salt field.

The following tables contain statistics on salt sold or used by producers in the United States by States and by methods of manufacture. Because of the small number of producers of salt in brine for chemical manufacture and of rock salt and evaporated salt in certain States, it is impossible to show either rock salt or salt in brine separately by States.

*Salt sold or used by producers in the United States, 1936–38, by States*

*Salt sold or used by producers in the United States, 1937–38, by methods of manufacture*

| Method of manufacture | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| Evaporated in open pans or grainers | 493,039 | $4,088,048 | 482,154 | $4,025,375 |
| Evaporated in vacuum pans | 1,603,825 | 9,424,260 | 1,479,806 | 9,072,224 |
| Solar evaporated | 362,627 | 1,342,153 | 330,441 | 1,352,568 |
| Pressed blocks from evaporated salt | 120,061 | 966,812 | 136,699 | 1,116,272 |
| Rock | 2,001,451 | 6,207,397 | 1,865,603 | 5,970,972 |
| Pressed blocks from rock salt | 28,981 | 240,251 | 36,258 | 281,109 |
| Salt in brine (sold or used as such) | 4,631,580 | 1,862,812 | 3,694,807 | 1,424,041 |
| | 9,241,564 | 24,131,733 | 8,025,768 | 23,242,561 |

*Evaporated salt.*—The output of evaporated salt, produced by 37 plants either from the original brine of wells and ponds or from brine obtained artificially by forcing the water into beds of rock salt and withdrawing it for processing by one of several methods in use, amounted to 2,429,100 tons valued at $15,566,439 in 1938. This includes 136,699 tons of cattle-salt blocks valued at $1,116,272 produced by 17 plants. Of the evaporated-salt plants, 22 used solar methods. Most of the salt comes from sea water in San Francisco Bay, Calif., and some from salt lakes and playas in Utah, New Mexico, Oklahoma, and Texas. Although a large quantity of solar salt is sold crude, that sold as table salt and for some industrial uses commonly is refined.

*Evaporated salt sold or used by producers in the United States, 1937–38, by States*

| State | 1937 | | 1938 | |
|---|---|---|---|---|
| | Short tons | Value | Short tons | Value |
| California | 362,917 | $1,785,854 | 343,008 | $1,912,637 |
| Kansas | 238,179 | 1,869,150 | 217,918 | 1,724,635 |
| Michigan [1] | 896,946 | 4,735,464 | 841,836 | 4,672,529 |
| New York | 372,635 | 3,562,823 | 340,137 | 3,378,167 |
| Ohio | 395,665 | 2,323,195 | 372,711 | 2,307,949 |
| Puerto Rico | 12,116 | 53,381 | 12,508 | 61,917 |
| Texas | 38,443 | 202,482 | 38,362 | 208,533 |
| Utah | 65,902 | 191,521 | 56,597 | 173,746 |
| West Virginia [1] | 128,715 | 713,421 | 129,568 | 721,490 |

| | 2,579,552 | 15,812,273 | 2,429,100 | 15,566,439 |

[1] Includes a quantity of salt content of brine for chemical use reported as evaporated salt with value as evaporated salt.
[2] 1937: Louisiana, New Mexico, and Oklahoma; 1938: Colorado, Louisiana, New Mexico, and Oklahoma.

*Rock salt.*—Production of rock salt reported by 21 plants aggregated 1,901,861 tons valued at $6,252,081. The total includes 36,258 tons of blocks valued at $281,109, produced by eight plants. New York again led in rock-salt production, followed by Louisiana, Kansas, and Michigan. These four States produced 92 percent of the total rock salt mined. Texas now produces considerable rock salt, and California, New Mexico, and Utah also are producers.

*Rock salt sold by producers in the United States, 1934–38*

| Year | Short tons | Value | Year | Short tons | Value |
|---|---|---|---|---|---|
| 1934 | 1,913,182 | $6,306,095 | 1937 | 2,030,432 | $6,447,648 |
| 1935 | 1,759,242 | 5,510,413 | 1938 | 1,901,861 | 6,252,081 |
| 1936 | 2,009,579 | 6,003,054 | | | |

*Salt content of brine.*—The quantity of salt in brine sold or used by producers for the manufacture of chemicals in 1938 was 3,694,807 short tons, a 20-percent decrease from the 4,631,580 tons in 1937 but still 11 percent greater than the 1930–34 average, and 13 percent greater than the 1925–29 average. Salt in brine was produced at 10 plants in 1938, excluding 2 plants where the product is reported as evaporated salt rather than as salt in brine. The greater part of this salt is used by the producers in the manufacture of their own chemical products, but some is now being sold in the form of brine to other manufacturers.

*Pressed blocks.*—The output of pressed blocks from both evaporated and rock salt, reported by salt producers, was 172,957 tons valued at $1,397,381. Blocks from evaporated salt, which comprised 79 percent of all reported, were made chiefly in Kansas and Michigan, but smaller quantities were produced in California, Texas, Ohio, Utah, Louisiana, and New York. Blocks from rock salt were made chiefly in Louisiana and Kansas, with small quantities in Texas and Utah. The figures herein reported do not include pressed blocks made from salt bought in the open market. The higher unit value of blocks is due largely to the labor involved in shaping and sizing the blocks and to the inclusion of other materials beneficial to cattle.

*Pressed-salt blocks sold by original producers of the salt in the United States, 1934–38*

| Year | From evaporated salt | | From rock salt | | Total | |
|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value |
| 1934 | 139,445 | $999,170 | 29,344 | $166,269 | 168,789 | $1,165,439 |
| 1935 | 126,005 | 900,040 | 24,691 | 156,002 | 150,696 | 1,056,042 |

## DISTRIBUTION

The following table was compiled from data furnished by the producers only, no account having been taken of reshipments. Information was supplied by all but two producers, and the necessary inclusion of their sales with shipments to "Other" States makes the figures for some States incomplete.

Digitized by Google

*Distribution (shipments) of evaporated and rock salt in continental United States, 1937–38, by States of destination, in short tons*

## VALUE AND PRICES

The average unit value for all salt at the mine, as reported by producers, rose 29 cents per short ton—from $2.61 in 1937 to $2.90 in 1938. Manufactured (evaporated) salt averaged $6.41 and rock salt $3.29 in 1938, 28 and 11 cents higher than in 1937.

Quoted prices of salt delivered at New York rose at the beginning of 1938 to $13.20–$13.80 (from $11.80–$12.80 in 1937) per ton for carlots of bagged rock salt and to $15–$15.60 (from $14–$14.50) for less than carlots. Those for vacuum common fine salt rose to $15.30–$15.70 (from $14.80) for carlots and to $16.50–$17 (from $15.50) for less than carlots. At the end of May 1938, prices for salt at New York rose again and remained nominally unchanged the remainder of the year, as follows: $13.20–$13.80 per ton for bagged rock salt in carlots and $15–$15.60 per ton in less than carlots; $15.30 per ton for bagged vacuum fine salt in carlots and $16.30–$21 per ton in less than carlots.

## PROGRESS IN TECHNOLOGY AND USES

The salt reported as salt in brine is consumed almost entirely in the manufacture of chemicals by the producers and does not enter the open market. Most of the other salt used in the manufacture of chemicals is evaporated salt which is marketed and sold by producers to chemical companies. As dry salt for chemical use is readily shipped, chemical companies using it need not be situated as close to the supply as those using brine for their raw material. Although most of the chemical companies that use brine are near the base of supply, one chemical company that owns its own brine-salt plant is more than 60 miles from the brine source. The brine is brought by gravity to the chemical plant through a 60-mile line of cast-iron pipes 14 inches in diameter, which is the longest pipe line of its kind in the world.

The utilization of the caustic soda produced with chlorine from salt is becoming increasingly important to chemical manufacturers. One method devised recently, based on treating the salt with nitric acid obtained by oxidizing synthetic ammonia, yields chlorine and a fertilizer-grade nitrate of soda. The production of salt cake by treatment of rock salt with sulfuric acid also is receiving attention.

Bureau of Mines engineers recently were asked to help solve a problem in pipe-line transportation at a western oil well where the company had difficulty because of the line freezing in cold weather, and they recommended the addition of salt. The water, unlike that at most oil fields, was fresh, and when the company pumped a saturated solution of salt water (roughly 4 tons of salt to 165 barrels of water) into its 20-mile line relief came in about 8 hours.

An ingenious system [3] of drying salt is claimed to produce a saving in the cost of steam at the Diamond Crystal Salt Division of the General Foods Corporation, St. Clair, Mich. The application of flow controllers to the Alberger and the interconnected triple-effect evaporator plants is another interesting development. The excess steam from the Alberger plant is utilized for the triple vacuum-pan evaporators, and the system of control takes care of any excess or deficiency of steam to the evaporators.

[3] Diamond, H. W., and Berry, N. E., Paper presented before the Conference on Instrumentation in the Process Industries at Carnegie Institute of Technology, Pittsburgh, Pa., Mar. 2, 1939, noted in Chem. and Met. Eng., vol. 46, No. 3, March 1939, p. 142.

Digitized by Google

One of the most interesting developments in 1938 was the manufacture of large crystals from purified molten salt. Experiments in the laboratories of Harvard University and the Massachusetts Institute of Technology on the manufacture of large single crystals of salt in cylindrical bars 2 centimeters in diameter and 30 centimeters in length have proved the practicability of such material for optical use. In 1938 the Harshaw Chemical Co., Cleveland, Ohio, undertook the manufacture of these crystals. Sometimes the single crystals, which are remarkably clear when correctly developed, weigh as much as 25 pounds. Careful maintenance of the proper temperatures during their manufacture and annealing is most important.

In 1938 interest was shown in the problem of eliminating corrosion and pitting in equipment for salt making and that exposed to salt or brine in processing industries. The practical commercial application of noncorrosive metals and alloys in salt making was described and an installation that had withstood 4 years' wear was cited in a London journal.[4]

The impurities in salt are some of the worst attackers of equipment. In most modern salt works these impurities are removed chemically from the brine before it goes to the refining pans. However, it is advisable to use the most resistant metals or alloys and thereby reduce corrosion and scaling, which are particularly serious in the vacuum-pan process of evaporation because they interfere with the transfer of heat. The use of Monel-metal wire cloth and woven-wire filtering and conveying belts also is said to be gaining. The resistance to corrosion of Monel metal is attributed to its high nickel content.

"Pink" salt is imported into the United States (20 to 25 thousand tons annually) chiefly for curing fish along the Atlantic seaboard. This salt is predominantly sea salt that is subject to the pink bacteria. The data given in a recent report [5] are of practical value to purchasers of salt for curing fish. This report states further that the California solar salt "contains over 99 percent sodium chloride, a much higher percentage than usually obtains in products from the European salines."

## FOREIGN TRADE [6]

The duty on salt was reduced under the trade agreements with the United Kingdom and Canada which were approved in November 1938 and became effective January 1, 1939. The duty on bulk salt was reduced 43 percent—from 7 cents per 100 pounds to 4 cents per 100 pounds, or a 24-percent ad valorem equivalent, under agreements with both countries. The duty on packaged salt was reduced 36 percent—from 11 cents per 100 pounds to 7 cents per 100 pounds, or a 14-percent ad valorem equivalent, under the agreement with Canada.

Total imports of dutiable salt, chiefly in bulk, are small compared with domestic production.

Imports of salt decreased 14 percent in quantity and 24 percent in value in 1938; most of the decrease was in bulk salt. Nearly one-half of the imports in 1938 were from Tunisia, which with Jamaica and Canada supplied 98 percent of the imported salt.

[4] Chemical Age, Monel Metal in the Salt Industry: Vol. 39, No. 1002, Sept. 10, 1938, p. 192. (Abstracted in Bureau of Mines, Mineral Trade Notes: Vol. 7, No. 4, Oct. 20, 1938, p. 29.)

[6] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

Exports of salt decreased 4 percent in quantity and 9 percent in value in 1938 compared with 1937. Shipments to Japan, which decreased 75 percent in 1937, increased 21 percent in 1938; however, shipments to Canada, Mexico, Cuba, Australia, and New Zealand, the other large markets for salt, decreased.

# MAGNESIUM COMPOUNDS, BROMINE, CALCIUM CHLORIDE, IODINE, SODIUM SULFATE, BORATES, AND MISCELLANEOUS SALINES

By PAUL M. TYLER and A. T. COONS [1]

SUMMARY OUTLINE

| | Page | | Page |
|---|---|---|---|
| General conditions | 1367 | Brucite | 1375 |
| Magnesite | 1368 | Other magnesium compounds | 1376 |
| Salient statistics | 1369 | Bromine | 1377 |
| Imports | 1370 | Calcium chloride | 1379 |
| Prices | 1370 | Iodine | 1380 |
| The industry in foreign countries | 1371 | Borates and other natural sodium compounds | 1382 |
| Technology | 1373 | Deeper drilling at Searles Lake | 1384 |
| Dolomite | 1374 | | |

The world's largest mineral deposit is the ocean, which contains per cubic mile some 128,300,000 tons of sodium chloride (common salt), 18,000,000 tons of magnesium chloride, 7,800,000 tons of magnesium sulfate, 5,900,000 tons of calcium sulfate, 4,100,000 tons of potassium sulfate, 600,000 tons of calcium carbonate, and 360,000 tons of magnesium bromide, together with a host of minor constituents. A cubic mile of sea water weighs 4,710,000,000 tons. The ocean covers 70.73 percent of the earth's surface, or 132,295,000 square miles; its average depth is 2.38 miles and its total volume 331,522,100 cubic miles.[2] In 1937 the Ethyl-Dow Chemical Co. pumped through its North Carolina plant 111,984,000 tons of ocean water to extract some thousands of tons of bromine. The unrecovered minerals, if extracted, would have been worth $136,595,370 at current prices and weighed 4,090,147 tons, according to figures made public by an affiliated corporation.[3] The elements not recovered included 0.071 ton of gold, worth $59,700; 2.22 tons of silver, $34,600; 13 tons of copper, $6,770; 195 tons of aluminum, $81,900; 206 tons of iron, $16,460; and 4.54 tons of iodine, $10,440. The intake of common salt totaled 3,005,000 tons (valued at $45,100,000), Epsom salts 764,000 tons, calcium chloride 165,700 tons, potassium chloride 85,900 tons, and strontium carbonate 226 tons, in addition to 68,900 tons of magnesium in the form of chloride.

Salts are ionized in solution, and percentage estimates as to quantities of specified compounds can be altered, owing to the various rearrangements and new chemical combinations into which the elements can be made to enter. Most of the sodium compounds of

Digitized by Google

commerce, in fact, are recovered by processing common salt, and these manufactured compounds compete with those recovered more or less directly from sea water and natural brines.

Virtually all natural waters carry dissolved salts, and the flowage from wells or springs frequently is highly mineralized. Occasionally water is pumped down into beds of soluble salts and then brought back to the surface in the form of quasi-artificial brines. All these more or less natural brines are used as sources not only of common salt but also of other saline minerals. Great closed basins where rainfall is deficient and streams have no outlet to the ocean contain salt lakes or, more often, playas and marshy beds of dried-up lakes ranging in size from small sloughs with a scanty encrustation of salts on the surface of the mud to thick beds several miles in extent. Unique in the variety of minerals is the large deposit in Searles Lake, San Bernardino County, Calif., which, after several false starts, was first utilized in 1917 as a source of potash and subsequently has yielded as joint products borax, trona, sodium sulfate, and in 1938, lithium compounds as well. Somewhat similar operations are conducted at Owens Lake in Inyo County, Calif., which, however, yields chiefly soda ash, sodium bicarbonate, and trona. Both lakes yield borax but sodium borate produced in the form of kernite from near Mojave, Calif., and small quantities of colemanite (calcium borate) are also produced in California.

Magnesite formerly was virtually the only magnesium compound of large industrial importance, but later large quantities of dolomite were used not only for making basic carbonate for heat-insulating coverings but also for other compounds and for refractories. Then magnesium salts, separated from Michigan brines, became important, and in 1937 even dead-burned magnesite began to be synthesized in California from sea-water bitterns. Brucite, the natural hydrate of magnesia, was first mined in Nevada in 1934. The interchangeability of magnesium raw materials is illustrated further by the utilization in Europe of carnallite and kieserite, which occur in the German (Stassfurt) potash deposits. As yet the separation of magnesia from talc and other silicate combinations does not appear to be economical, but olivine (discussed in the Minor Nonmetals chapter of Minerals Yearbook) is mixed with magnesite and utilized for refractories of the "Forsterite" type.

Most important of all saline minerals is common salt, which is discussed in a separate chapter of Minerals Yearbook 1939. Potash likewise is treated in a separate chapter. Salt-works byproducts, however, including not only magnesium compounds but also calcium chloride, bromine, and iodine, are no longer included in the chapter with salt but are discussed in this chapter with magnesite and magnesium compounds, which in former years were treated separately in the Yearbook.

## MAGNESITE

Following the usual pattern of refractory-product sales (which are more sensitive than consuming industries to an oncoming recession and do not pick up again until well along in the ensuing recovery), the apparent consumption of dead-burned magnesite in the United States in 1938 was 54 percent less than it was in 1937, whereas open-hearth steel production dropped only 44 percent. Total sales of

Digitized by Google

domestic and imported caustic calcined magnesite dropped 31 percent and those of crude magnesite, never important, 52 percent.

The Northwest Magnesite Co. (executive offices, Farmers Bank Building, Pittsburgh, Pa.) operated two or three of its six kilns (300 tons total daily capacity) at Chewelah, Wash., for 8 months of the year. Crude magnesite was mined at both the Finch and Allen-Moss properties. Some of the deposits in this area measure hundreds of feet in width and merge indefinitely into the adjoining rock mass, so that their boundaries can be determined only by sampling and chemical analysis. The magnesite is interfingered with dolomite and contains disseminated calcite, talc, serpentine, quartz, and shale. Hitherto only the best parts of the deposit have been mined and great quantities of magnesite-bearing waste have been rejected. The Bureau of Mines and the State Electrometallurgical Research Laboratories, Pullman, Wash., in cooperation have worked out processes for beneficiating this material successfully by froth flotation. Electrothermal methods resembling those employed at Radenthein, Austria, are also being perfected for manufacturing magnesium metal, using power from Grand Coulee Dam.

[1] Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.
[2] Average receipts f. o. b. mine shipping point.

The new sea-water plant of the Westvaco Chlorine Products Corporation (executive offices, 405 Lexington Avenue, New York, N. Y.) at Newark, Calif., was operated successfully in 1938, its product being sold throughout the year to the same customers who formerly purchased material from the company mines. The product is so nearly identical to the mine product from the standpoint of performance

Digitized by Google

that certain users may not even have realized the source of the material they received. The Tycrete Chemical Corporation (Chula Vista, Calif.) reported production of crude magnesite in Imperial County, which it converted in a small rotary kiln into caustic-calcined magnesite for building uses.

A small quantity of magnesite was produced by the Eastern Magnesia Talc Co., Inc. (206 Bank Street, Burlington, Vt.) as a byproduct of its talc-milling operations at Johnson, Vt. The material is quite high in iron oxide, and a substantial tonnage should be available in 1939.

## IMPORTS

The United States, usually a large buyer of Austrian dead-burned magnesite, reduced its imports of that material to 6,691 tons in 1938 from 24,271 tons in 1937, or 72 percent. Imports from Czechoslovakia declined 64 percent, whereas those from Manchuria (Kwantung) were less drastically curtailed. Of special interest was the relatively large importation from Japan, hitherto an insignificant source. It is believed that the 907 tons imported from Japan in 1938 came from newly exploited deposits in Chosen. Korean magnesite previously had been offered at around $10 a ton f. o. b. shipping point, and it was reported that Japanese vessels had agreed to transport it to any United States Atlantic port for $3 a metric ton, making the landed cost far below that of European magnesite.

With the announcement in August 1938 that the United States intended to negotiate a trade agreement with Venezuela, notice was given of possible reduction in the tariff protection on domestic magnesite that has been operative since 1922.

*Magnesite imported for consumption in the United States in 1938, by countries and classes*

## PRICES

At the beginning of the year the Engineering and Mining Journal was quoting dead-burned magnesite at $25 a short ton f. o. b. California or Washington (State) shipping points. For other products,

Digitized by Google

its quotations f. o. b. California were, nominally: Artificial periclase, 94 percent MgO, $65; 90 percent, $35; caustic, 95 percent MgO, white color, $40; 85 percent MgO, no color standard, $37.50 per ton. By May the quotation on dead-burned magnesite was reduced to $22 a ton, but in September the price of the California product was restored to $25. Quotations on other products remained unchanged throughout the year.

The average values realized on domestic sales, as calculated from returns from the producers to the Bureau of Mines, held up fairly well, although the slight gains made during the preceding 2 years were canceled. The figures for crude, caustic calcined, and dead-burned magnesite, respectively, were $13.42, $30.88, and $18.87 per ton in 1938 compared with $14.96, $31.04, and $19.21 in 1937.

## THE INDUSTRY IN FOREIGN COUNTRIES

*World production of magnesite, 1933–37, by countries, in metric tons* [1]

[3] Magnesitic dolomite.
[4] Data for production not available; value reported as follows: 1936, $768,742; 1937, $677,207.
[5] Exports, less imports, of crude and sintered magnesite, the sintered being reduced to crude on the basis of 2.1 tons crude to 1 ton sintered.
[6] Serbia only.

*Austria (Germany).*—The "Anschluss" with Austria makes Germany a potentially important exporter of magnesite instead of a large importer. Following this coup d'état the name of the Austro-American Magnesite Co. of Radenthein was changed to Austrian Magnesite Co. (Österreichische Magnesit A. G.), but the majority stock interest is reported to be still held in the United States. About 50 percent of the Austrian exports of magnesite in 1937 were supplied by the Veitscher Magnesitwerke. A third company, the Styrian Magnesite Industry Co., Ltd., produces mostly caustic-calcined magnesite and has not been a member of the cartel comprising the other Austrian and Czechoslovak producers.

Deliveries of Austrian magnesite to Germany doubtless were higher in 1938 than in 1937 because production was probably greater and

Digitized by Google

exports to other countries decreased. Exports of caustic calcined magnesite in 1938 were only 3,950 metric tons and of dead-burned 42,150 tons. Virtually no raw magnesite went outside the country in 1938, but 38,497 tons of magnesite brick and plates were exported, chiefly to France, England, and Italy. The United States is normally the largest buyer of Austrian dead-burned magnesite, but in 1938 exports to the United States were only 13,900 tons compared with 23,430 tons in 1937, and those to England declined moderately to 12,400 tons compared with 13,990 tons in 1937.

*Canada.*—Magnesitic dolomite, an intimate mixture of magnesite and dolomite, occurs at Kilmar and Harrington East, Argenteuil County, Quebec. In 1937 operations that previously were wholly open-cut were extended underground, and a modern new tunnel kiln was installed at the property of the Canadian Refractories, Ltd. This kiln, the fourth of its kind in the world, is 88 feet long and attains a temperature of 3,100° F. According to a statement by the Canadian Department of Mines and Resources, the products marketed at present include caustic calcined (for making flooring compositions and tile), dead-burned or grain material, bricks and shapes (burned and unburned), and refractory cements (finely ground).

In 1938 the reported value of the products was $420,261 compared with $677,207 in 1937 and $768,742 in 1936. The drop in 1938, however, was not quite as great as these figures suggest, because the reported value includes only that of the calcined material sold plus the cost value of the calcined magnesitic dolomite used for further manufacture by the producing company. In former years the sales value of manufactured products, such as refractory bricks and other similar materials, was also included. Imports of magnesitic dolomite into the United States are shown later in the chapter in the section on dolomite.

*Chosen.*—It is reported[4] that the Korean Government has decided to permit private companies to mine magnesite at Zuisen, Kankyo Hokudo. These deposits, estimated to contain some 3 billion tons, have been closed in the past.

*France.*—According to L'Echo des Mines et de la Metallurgie (January 20, 1939, p. 23), prices and deliveries of dead-burned magnesite and magnesite brick from Austria were not affected by the union with Germany. France imports crude magnesite chiefly from Greece, and supplies were not particularly abundant at prices ranging from 31s. 6d. to 35s. a metric ton ($7.90 to $8.75) for small cargo lots. This material, which runs 45 percent MgO, is used for making metallic magnesium, magnesium chloride, and Sorel cement, and a little is used for magnesium nitrate. Quotations for caustic calcined magnesite, 85 to 90 percent MgO, ranged from £4 10s. to £6 10s. a ton ($22 to $32).

*Union of South Africa.*[5]—Magnesite has been produced continuously on a small scale in the Eastern Transvaal. The Althorpe mine is situated in the Barberton district about 10 miles east of Kaapmuiden, near the main road and railway to Lourenco Marquea, which is 100 miles away. There are other mines in the same district and near Lydenburg. The magnesite occurs in decomposed serpentines

Digitized by Google

and is exceptionally pure, averaging more than 97 percent $MgCO_3$, 0.85 percent $CaCO_3$, 1.20 percent $SiO_2$, and 0.48 percent $Fe_2O_3$. The yield in magnesite ranges from 10 to 25 percent of the ground removed by open-cut operations but may be higher in adit mining. After hand-sorting, much of the material is calcined in vertical shaft kilns using charcoal, and the product of the kilns is hand-sorted before crushing and bagging. Hitherto almost the entire output has been consumed more or less locally for flooring compositions, the gas being compressed and bottled for soda water, but owing to the purity of the material, the extent of the deposits, and the favorable situation of the mines for overseas shipments, an important export business may develop.

*U. S. S. R.*—In response to a request from the Bureau of Mines, the American Embassy in Moscow reports that no magnesite-production statistics have appeared in Soviet publications since 1933. The principal source is the Satka mine, which yields crude magnesite averaging 46.2 percent MgO. The output is used domestically as caustic calcined magnesite and dead-burned magnesite, although some of the latter is exported as grain and a minor amount as brick. Large-scale experiments have been made with the object of utilizing magnesite in the production of metallic magnesium. The capacity of the Satka works is about 80,000 tons a year.[6] The magnesite from these deposits, which are situated in the Western Ural Mountain district, is not quite as finely crystalline as the Styrian (Austrian) magnesite and is grayish white, but otherwise it is similar. Additional large deposits have been reported near Lake Baikal, East Siberia.

## TECHNOLOGY

Under the cooperative research program at Pullman, Wash., supervised by H. A. Doerner, of the Bureau of Mines, three methods of commercially beneficiating low-grade magnesite have been developed and described.[7] Large-scale experiments may be required to determine which is most economical in practice. The first method involves selective calcination and mulling, followed by sizing. The second method is identical, except that the concentrate produced from treating low-grade ore is concentrated further by flotation. The third method requires no preliminary calcination but involves two-stage flotation. Attempts to float magnesite directly from low-grade ores gave poor results; owing to the difficulty of depressing talc, the grade of product and recovery were low. The highest-grade product for a given recovery was obtained by first floating away calcite and most of the siliceous minerals and then floating the magnesite away from the dolomite in a second step.

According to German Patent 655,793 (January 22, 1938)[8] magnesite may be floated directly from quartz, serpentine, and calcite by adding sodium oleate, water glass, and an acid metal salt, such as aluminum chloride.

A recent British patent (M. Levi, British Patent 473,953) covers a light-weight, heat-insulating material bonded by calcined magnesite and magnesium chloride (with or without sand, sawdust, or cement) and mixed with rice husks or hulls of other seed grains which are used whole to obtain air pockets.[9]

The development of chemically bonded magnesite brick has increased the useful range of magnesite linings for rotary cement and dead-burned dolomite kilns. Normally, where burning-zone linings of 70-percent alumina brick cost approximately $40 per foot, linings of unfired magnesite brick may cost $100 per foot. Where operating conditions are most severe, however, the additional cost has been more than offset by longer life and more regular operation.[10]

## DOLOMITE

In 1938 sales of dead-burned dolomite by domestic producers dropped to 366,626 short tons valued at $3,095,355 compared with 617,706 short tons, valued at $5,217,833 in 1937, and 596,751 tons, valued at $4,887,243 in 1936. Most of the dead-burned dolomite is used for furnace bottoms, but substantial quantities of specially prepared material are sold to the glass industry under the trade name Calcimag. Single-burned dolomite or high-magnesium lime is classed in the Bureau of Mines statistics merely as "lime," although some of it is valued for its magnesium content. Increasing quantities of raw dolomite and high-magnesium limestones are used in agriculture to correct acidity and as a source of magnesium. The need for magnesium in the soil has been increasingly recognized in recent years.

Imports of dead-burned dolomite, reported separately since June 18, 1930, comprise principally impure magnesite or the so-called magnesitic dolomite dead-burned in Canada for steelworks refractories. This product, known as "Basifrit," usually contains 62 percent MgO and 21 percent CaO. By an ingenious method of calcination the usually troublesome lime content is rendered inactive, and it is claimed that this product is quite as useful for furnace bottoms as grain magnesite containing a maximum of about 4 percent CaO. In 1938 an American company, Basic Dolomite, Inc., having bought the formula and acquired a license to make a similar product, is reported to have begun its manufacture in the United States. Brucite, mined near Luning, Nev., is used as an admixture with dolomite to raise the magnesia content.

Originally the Canadian material was imported into the United States free of duty as "magnesite," but after the tariff act of 1922 levied a duty on magnesite it was reclassified and became dutiable under paragraph 214 of that act at 30 percent ad valorem. Under the first reciprocal trade agreement with Canada it was specifically described as "dead-burned basic refractory material containing 6 per centum or more of lime and consisting chiefly of magnesia and lime," and the duty was reduced on January 1, 1936, to 27½ percent ad valorem. In the second trade agreement between the United States and Canada, effective January 1, 1939, the minimum lime content was raised to 15 percent, and the duty was lowered further to 20 percent. The average lime content of all imports of magnesitic

Digitized by Google

dolomite from Canada has been well over 15 percent and the average value has ranged from $22.62 a short ton (1932) to $25.79 (1934).

[1] Reported as "dead-burned basic refractory material" since 1935.
[2] 1930, Czechoslovakia; 1935–36, United Kingdom.
[3] June 18 to December 31 only.
[4] Duty lowered from 30 to 27.5 percent on January 1, 1936.

## BRUCITE

After sundry set-backs, brucite mining has just become established on a moderately extensive scale. The deposits near Luning, Nev., are of enormous extent and high purity; but transportation difficulties proved a handicap, and the material was not readily accepted as an interchangeable substitute for magnesite. Small quantities of this natural hydrate of magnesia, $Mg(OH)_2$, have been employed in petroleum refineries and for making magnesium compounds, but the important outlet at present is in the manufacture of furnace refractories, largely to increase the slag resistance of dolomite. Mining operations are conducted under lease from the United States Brucite Corporation by Basic Ores, Inc., a subsidiary of the principal consumer, Basic Dolomite, Inc. (845 Hanna Building, Cleveland, Ohio). For 1938 statistics on the production of brucite are included with those of "Other magnesium compounds." Previously they were reported only in a miscellaneous group, although the present operators who started work in October 1936 shipped substantial tonnages in that year and increased output materially in 1937. Prior to 1936 occasional carloads had been shipped for experimental purposes, but the quantity was inconsequential.

An excellent description of the Nevada deposits was published some years ago.[11] Much of the material runs less than 2 percent silica, less than 1 percent alumina, and about 0.75 percent iron oxide. Brucite occurs in conjunction with magnesite in Washington, and a small quantity has been used locally for carving into ornaments. The mineral has been noted at Hoboken, N. J., at Brewster, N. Y., and in Pennsylvania. Specimens have been found also in British Columbia, in Quebec, and in a few places in Europe, notably on certain islands off the coast of Scotland. Reported deposits in the Russian Caucasus may have commercial significance, but none are known that compare in size and purity with those in Nevada.

Digitized by Google

In 1938, however, brucite-bearing limestones were discovered at Rutherglen, Ontario, and at Bryson, Quebec, and this material is being considered for use in refractories and for making magnesium metal. Large deposits of hydromagnesite occur near Atlin and at other localities in British Columbia. According to a recent report, these may be utilized; the material is much superior to that found in the Reinosa district, Province of Santander, Spain, which has been mined more or less extensively notwithstanding its contamination with dolomite.

## OTHER MAGNESIUM COMPOUNDS

The total quantity of magnesium compounds other than magnesite and dolomite produced from natural sources and sold or used in the United States was 70,733 short tons valued at $1,688,570 in 1938, an increase over the 64,777 tons valued at $1,578,527 reported for 1937 and the 63,841 tons worth $1,629,725 for 1936.

In 1938, as in former years, the principal items were magnesium chloride and sulfate recovered from brine wells and sea water. However, a little carbonate, oxide, and hydroxide also are recovered from these sources, and 1938 figures include for the first time the increasingly important output of brucite, which was produced commercially in Nevada as early as 1934, but the output was not included in the Bureau of Mines figures for magnesium salts until 1938. As shipments of brucite in those years were much less than in 1938 and are not very large even yet, this omission is not especially serious and may be corrected within a year or two with the consent of the producer.

Production of technical or basic carbonate of magnesium is more important even than that of the sulfate or chloride, but most of it is made from dolomite. In 1937 the Bureau of the Census reports the production of such carbonate, probably including the small quantity recovered from bitterns, as 6,505 short tons valued at $788,215 compared with 7,301 tons valued at $877,741 in 1935, the first year for which separate statistics are available. These figures, which cover seven establishments, do not include quantities (probably much larger) consumed at producing plants in making magnesia pipe coverings and other kinds of molded insulation. Total domestic productive capacity for the dry carbonate was estimated by the Tariff Commission as 13,500 tons in 1936 but subsequently has been increased. The production made for sale is used mainly in rubber goods, printing inks, paints, varnishes, pigments, and free-flowing table salt.

According to reports received by the Bureau of Mines natural magnesium chloride was recovered by the Dow Chemical Co., Midland, Mich., with various other products from its natural brines and by the Westvaco Chlorine Products Corporation from its sea-water bitterns at Chula Vista, Calif. Epsom salt (sulfate) was produced by the Dow Chemical Co. and by C. A. Kearney Co., which operates at Epso Lake, Tonasket, Wash.; the epsomite deposit at Medicine Bow, Albany County, Wyo., was not operated in 1938. Carbonate was reported by three companies: Plant Rubber & Asbestos Works at Redwood City, Calif.; Marine Chemicals Co., Ltd., at South San Francisco, Calif.; and Morton Salt Co. at Manistee, Mich. The Marine Chemicals Co., Ltd., also reported production of magnesium oxide and magnesium hydroxide (paste, powder, and milk of mag-

Digitized by Google

nesia). As previously noted, brucite is mined at Luning, Nev., by Basic Ores, Inc.

Under the reciprocal trade agreement with the United Kingdom, effective January 1, 1939, the duty on imported precipitated magnesium carbonate, over 60 percent of which came from the United Kingdom in 1937, was reduced from 1½ cents to 1 cent a pound. Production of magnesium sulfate in Canada, all from the Kamloops district of British Columbia, declined to 470 tons valued at $9,400 in 1938 compared with 727 tons valued at $14,456 in 1937.

*Magnesium compounds imported for consumption in the United States, 1930–38*[1]

[1] In addition to the items reported separately, 3,668,091 pounds of calcined magnesium sulfate or calcined kieserite (not fertilizer) valued at $30,291 were imported in 1935, 5,439,651 pounds valued at $44,664 in 1936, 8, 233,726 pounds valued at $71,889 in 1937, and 6,386,795 pounds valued at $66,470 in 1938. Also 11,200 pounds of "manufactures of carbonate of magnesia" valued at $489 were imported in 1935; 13,056 pounds valued at $562 in 1937; and 5,600 pounds valued at $209 in 1938; none recorded in 1936.

[2] Not reported separately but included in the "magnesium salts and compounds, n. s. p. f."—372,291 pounds valued at $29,355 in 1936; 140,110 pounds valued at $20,462 in 1937; and 95,129 pounds valued at $17,146 in 1938.

A new magnesium product, activated magnesia, is claimed to possess properties that make it suitable for use as a decolorizing, neutralizing, or absorbing agent in industrial processes. It is made by heating precipitated magnesium hydroxide until 80 to 85 percent has been converted into oxide. The typical analysis shows 70.84 percent MgO, 14.38 percent $Mg(OH)_2$, 8.78 percent $MgCO_3$, 1.36 percent $MgSO_4$, and 3.42 percent $CaCO_3$, the remainder being silica, common salt, and oxides of iron and aluminum. The absorptive power of the dry powder for coloring matter is said to be 5 to 10 times that of bentonite or fuller's earth. It also speeds up chemical processes requiring a neutralizing agent. The activity of the product depends chiefly on the temperature of calcination and proper distribution of the heat.[12]

## BROMINE

Notwithstanding the recession in most lines of business in 1938, the production of bromine in the United States, as reported by producers to the Bureau of Mines, continued to increase, as it has in every year since 1932. The 1938 output was 16,162 short tons valued at $6,610,056 compared with 13,100 tons worth $5,180,177 in 1937 and 10,305 tons valued at $4,038,438 in 1936. Not until 1923 did bromine begin to be used in the form of ethylene dibromide for making tetraethyl lead compounds for antiknock motor fuels, and as recently as 1925 the output was only 783 tons. The latest statistics, therefore,

[12] Chemical Trade Journal and Chemical Engineer, Activated Magnesia: Vol. 102, No. 2662, May 27, 1938, p. 440. (British Patent 483,096, Apr. 12, 1938.)

Digitized by Google

reveal an increase of almost 2,000 percent in 13 years. In the last 3 years the output of bromine has virtually doubled. Domestic demand for motor fuel of all types also has increased but only from 434,810,000 barrels in 1935 to 521,657,000 in 1938, or roughly 20 percent for the 3-year period. In the late 1920's the rate of increase in gasoline demand was about 20 percent a year, but it slowed down until in 1932 there was a slight recession. Although the uptrend was resumed later, the advance in 1938 over 1937 was barely perceptible, whereas the advance in bromine requirements was 23 percent.

Deposits of many minerals are worked out eventually, but bromine is mined from the inexhaustible reservoir of the ocean. Sea water contains only 1 pound of bromine in 2,000 gallons, yet it can yield even this small quantity economically by modern processes. In recent years the bulk of the domestic supply has come from the seaside plant at Kure Beach near Wilmington, N. C. The capacity of this plant has been increased repeatedly. Future growth is forecast in the following citation from a report of the Interstate Commerce Commission:

> Commercial operation of the dibromide plant at Kure Beach was begun in 1934 * * * the volume of traffic has ranged from 147,267 gallons of alcohol and 87,000 gallons of dibromide in the year ending June 30, 1934, to 818,855 gallons of alcohol and 1,343,000 gallons of dibromide in the 1938 fiscal year. Ultimately the movement of dibromide from Kure Beach to Carney's Point, N. J., is expected to reach 22,000,000 gallons. Dibromide also moves from Kure Beach to North Baton Rouge, La.

At consuming works the bromine compound is treated further with an alloy of metallic sodium and lead to make the tetraethyl lead fluid that is added in varying proportions to many of the better grades of so-called "ordinary gasoline" as well as to the special high-test motor fuels. On January 31, 1939, the Interstate Commerce Commission authorized a reduction of railroad rates on tank cars of ethylene dibromide from Wilmington, N. C., to Carney's Point, N. J.; the new rate is 26 cents per 100 pounds as against 89 cents formerly. The return rate between the two points on ethyl alcohol used in the process was reduced from 52 to 26 cents.

Other commercial sources of bromine in the United States include brine wells in California, Michigan, Ohio, and West Virginia. Although this country is the largest producer of bromine in the world and probably exports more than it imports, bromine is recovered in several other countries from brine wells and salt-works bitterns and is an important byproduct of the extensive potash industry that has sprung up in Palestine on the shores of the Dead Sea. In an effort to expand the demand for this bromine, the Daniel Sieff Institute at Rehoboth has investigated possible new uses of bromine derivatives as insecticides. Exports of bromine from Palestine are chiefly to the United Kingdom. Inasmuch as some of the product is warehoused at Port Said, statistics from different sources are not always comparable, but it would seem that total exports declined somewhat in 1938 after reaching a peak of 533 metric tons in 1937. Bromine-recovery plants utilizing salt-works bitterns are projected on a large scale in Italy and Japan, but so far no plants using raw sea water are known to have been built outside of the United States.

The average value of the domestic output of bromine in 1938, as reported to the Bureau of Mines by producers, was 20.4 cents a pound, or a trifle more than in 1937. This is a nominal figure, as most of the

Digitized by Google

bromine was shipped in the form of ethylene dibromide, potassium and sodium bromide, and other compounds.

The aggregate value of imports of bromine and bromine products rose to $277,527 in 1938 compared with $225,268 in 1937 and $258,337 in 1936. The main item of imports, ethylene dibromide from Germany, advanced 23 percent over the 1937 quantity and almost equaled that for 1936. Late in 1938, however, the Bureau of Customs ordered assessment of a countervailing duty on this product of 3.775 cents a pound applicable only to imports from Germany and offsetting a bounty paid by the German Government.

## CALCIUM CHLORIDE

Production and sales of calcium chloride and mixed calcium-magnesium chloride obtained directly from natural brines increased slightly in 1938 over 1937 but fell short of the all-time record of 1936. Calcium chloride is also produced as a byproduct of soda ash in the Solvay process, but sales of this material are not included in the table that follows, as the calcium comes from limestone and the chlorine mostly from sodium chloride that is elsewhere reported as salt in brine.

Imports of calcium chloride for consumption in 1938 were 1,647 short tons valued at $21,174, of which 1,605 tons valued at $20,703 came from Germany. The quantity imported in 1938 is the smallest since separate statistics became available in 1922 and compares with 2,205 tons worth $24,908 in 1937 and a maximum of 9,263 tons valued at $100,223 in 1928. Exports have fluctuated during the past decade from a high of 30,736 tons worth $525,179 in 1935 to a low of 15,425 tons and $362,658 in 1929. In 1938 they were 24,118 tons valued at $396,981.

In 1938 the Federal Trade Commission filed a complaint against four leading manufacturers and their Calcium Chloride Association, alleging price fixing and more specifically that they had (1) maintained a uniform zoning system for the United States; (2) suggested retail prices to their individual dealers and distributors; (3) exchanged information with reference to their prices and annual output; and

Digitized by Google

(4) made identical bids. It was alleged further that expenses of the association were prorated according to estimated yearly incomes, Dow Chemical Co. and Solvay Sales Corporation paying 32½ percent each and Columbia Alkali Corporation and Michigan Alkali Co., 17½ percent each, also that each of the other three companies contributes an additional $12,500 annually for right to use a manufacturing process patented by the Dow Chemical Co.

Later the Commission issued a cease and desist in respect to the four companies and closed without prejudice its case against the Solvay Process Co. (which owns the Solvay Sales Corporation) and the Calcium Chloride Association. According to its own statement, the activities of the association "consist among other things, of direction and control of advertising, publicity, research, and engineering promotion of the various uses of calcium chloride, which are principally for dust laying and stabilization in road building, ice control, curing concrete for roads, and treatment of dustless coal and brine for refrigeration."

Of these companies only the Dow Chemical Co. produces calcium chloride from natural brines. Other companies that reported production of calcium chloride or calcium-magnesium chloride to the Bureau of Mines include Great Lakes Chemical Corporation, Filer City, Mich.; Michigan Chemical Corporation, Saint Louis, Mich.; Rademaker Chemical Corporation, Eastlake, Mich.; Pomeroy Salt Corporation, Pomeroy, Ohio; J. Q. Dickinson & Co., Malden, W. Va.; Liverpool Salt Co., Hartford, W. Va.; Ohio River Salt Corporation, Mason, W. Va.; and Westvaco Chlorine Products Corporation, South Charleston, W. Va.

## IODINE

The iodine industry of the United States began its second decade under auspicious circumstances. Started in 1928 and threatened with early extinction by progressive reductions in the price of Chilean iodine, it managed in 1938 to increase production, continuing the recovery that began in 1937. Imports of crude iodine, all from Chile, dropped sharply to 570,532 pounds valued at $464,303 from the record quantity of 1,967,148 pounds valued at $1,784,491 in 1937. Owing

Digitized by Google

to the importers' policy of maintaining large stocks, these figures disclose nothing as to consumption trends; fluctuations in other years have been almost as violent.

*Iodine produced in the United States, 1934–38*

| Year | Pounds | Value | Year | Pounds | Value |
|---|---|---|---|---|---|
| 1934 | 284,604 | $342,957 | 1937 | 299,286 | $242,422 |
| 1935 | 245,696 | 248,654 | 1938 | (1) | (1) |
| 1936 | 233,925 | 212,635 | | | |

| 1934 | 1,481,123 | $2,134,979 | 1937 | 1,967,148 | $1,784,491 |
| 1935 | 375,819 | 420,793 | 1938 | 570,532 | 464,303 |
| 1936 | 592,217 | 558,326 | | | |

Definite efforts have been made to expand demand for iodine, which is available in almost unlimited quantities in Chile as a byproduct of nitrate manufacture. Iodine has been added to salt and to municipal-water supplies as a preventive of goiter. It is an ingredient in a variety of medicines for combating various ills of man and beast, is a valuable laboratory reagent, has important uses in photography, and is employed in many other industries, but the principal prospect for largely increasing consumption is its use in animal feeding. During 1938 research workers at the University of Wisconsin reported that they had developed a permanent, simple means for stabilizing the iodine content of salt, limestone, and other mineral feed mixtures. In England the Nitrate Corporation of Chile, Ltd., announced the formation of an Iodine Education Bureau. This bureau will collect and disseminate scientific information on iodine and will collaborate with scientific institutions in experimental research to extend the knowledge of iodine, with special reference to its use in human and animal nutrition. It is not engaged directly in sales activities.

Although domestic production was begun in 1928 in Louisiana and later in California it did not become commercially important until 1930, when the General Salt Co., Long Beach, Calif., reported a substantial output; smaller quantities were produced by the Dow Chemical Co. and the Deepwater Chemical Co., Ltd. In 1932 the Jones Chemical Co., a subsidiary of the Dow Chemical Co., was producing iodine at Long Beach, Calif., and Shreveport, La.; in 1933 the name of this company was changed to Io-Dow Chemical Co., and its Louisiana operations were abandoned. The California plant of this company has operated continuously since it was started, and because of its superior processes and financial resources has become the dominant factor in the domestic industry. The only other producer in 1938 was the Deepwater Chemical Co., which resumed operations in 1936 under process patents controlled by Dow.

One of the recovery processes owned by the Dow Chemical Co. was patented recently (United States Patent 2,144,119, January 17, 1939). The iodine liberated from brine and removed therefrom by adsorption upon activated carbon or charcoal is precipitated on the anode of an electrolytic cell employing the compressed iodine-charged carbon as cathode.

Digitized by Google

The Chilean Nitrate & Iodine Sales Corporation reported sales of 832,290 kilograms of iodine for the fiscal year ended June 30, 1938; this figure compares with reported totals of 884,965 kilograms in 1936–37, 749,335 in 1935–36, and 462,474 in 1934–35. In June 1937 a 3½-year agreement was signed with Japan regulating Japanese exports, the exact amount to be determined in advance on July 1 of each year, in accordance with average selling prices of the preceding year, but in no event to be more than 70 or less than 25 tons. Under this agreement the Japanese firms were ordered by their Government to organize an export guild. France, which has a small domestic industry on the Brittany coast, using kelp, reestablished its import quotas on crude iodine on September 1, 1938.

The price of crude iodine was pegged for a number of years at the equivalent of almost $4 a pound. It was commonly assumed that Chilean nitrate producers could have sold it profitably at 25 cents a pound, but this was unnecessary as long as almost the only competition was from seaweed iodine costing $2 or $3 a pound. Following the development of domestic production from California oil-field waters, the price was dropped until on October 10, 1936, it was down to 81 cents a pound. In 1938, however, it was revised upward to $1.02. This is the world price quotation, other currencies being referred back to American exchange.

## BORATES AND OTHER NATURAL SODIUM COMPOUNDS

Except for a sharp decline in borax shipments due partly to greatly reduced exports, recoveries of sodium compounds, other than common salt, from natural brines and saline deposits in the United States were well-maintained in 1938, faring better than the production of similar compounds from chemical plants. Sales of natural sodium sulfate increased slightly in quantity to 80,210 short tons valued at $596,812 compared with 80,053 tons valued at $599,266 in 1937. Although sales of natural sodium carbonates (chiefly soda ash but also bicarbonate and trona) declined 4 percent in quantity they increased 4 percent in value, amounting to 100,010 tons worth $1,235,328 as against 104,711 tons valued at only $1,191,485 in 1937. Production of sodium borates in 1938 totaled 219,513 tons valued at $4,570,316, a 39-percent decrease in tonnage from the 1937 figures (358,898 tons, $7,232,897). Owing to the importance of sodium borates the total for the group decreased to 399,733 tons valued at $6,402,456, or 26 percent less than the 1937 total of 543,662 tons worth $9,023,648.

*Natural sodium compounds (other than NaCl) sold or used by producers in the United States, 1934–38*

| Year | Carbonates [1] | | Sulfates [2] | | Borates [3] | | Total | |
|---|---|---|---|---|---|---|---|---|
| | Short tons | Value | Short tons | Value | Short tons | Value | Short tons | Value |

The entire output of sodium carbonates came from Owens Lake and Searles Lake, Calif. The Pacific Alkali Co., at Bartlett, and the Natural Soda Products Co., at Lone Pine (Keeler), operated at Owens Lake, Inyo County. At Searles Lake, San Bernardino County, the American Potash & Chemical Corporation, Trona, and the West End Chemical Co., Westend, also produced carbonates. All these companies except the Natural Soda Products Co. produce borax, and the American Potash & Chemical Corporation also is one of the largest producers of sodium sulfate, as well as of potash and lithium compounds, all as coproducts of Searles Lake brines. A credible estimate of production of soda ash from all domestic sources, including chemical plants using common salt as raw material, indicates a 20-percent decline in 1938 compared with 1937. The Bureau of the Census reported for 1937 a production for sale of 2,323,759 tons of soda ash valued at $33,768,770 and 142,161 tons of refined sodium bicarbonate valued at $3,606,271; in addition, 713,662 tons of soda ash was consumed in the same establishments where it was made.

The slight increase in domestic sales of natural sodium sulfate is all the more remarkable in the face of a sharp curtailment in imports of this material. Reflecting slower activity at southern kraft-paper mills, the total imports of salt cake dropped to 142,429 short tons from 220,176 tons in 1937; however, owing to the enormous increase in consumption of sodium sulfate during the last decade, the 1938 total was larger than that for any year previous to 1936. The bulk of the imports still come from Germany, but receipts from Chile increased substantially to 26,079 tons in 1938 from 17,120 tons in 1937 and 687 in 1936. No data are available as to domestic production from chemical works during the year under review. In 1937, according to the Bureau of the Census, the total output of salt cake from both chemical works and natural sources was 269,177 tons, of which 241,347 tons worth $2,367,616 were for sale. Sales of anhydrous (refined) sulfate were 21,797 tons valued at $312,285; Glauber's salt, 31,934 tons, $490,660; and niter cake, 22,983 tons, $521,601.

The Ozark Chemical Co., Tulsa, Okla., produces a large quantity of sodium sulfate as salt cake from deposits at Monahans, Ward County, Tex. This material was shipped from three new localities in 1938—the Arizona Chemical Co. (subsidiary of the American Cyanamid Co., New York, N. Y.) reported production in Texas from O'Donnell, Lynn County, and from Brownfield, Terry County, and the Salt Lake Sodium Products Co. made shipments from its plant near Salt Lake City, Utah. In 1938, as in former years, small quantities of Glauber's salt were produced in Wyoming near Rawlins, Carbon County, by the Iowa Soda Products Co. of Council Bluffs, Iowa, and at Casper, Natrona County, by W. E. Pratt. Saline deposits carrying both carbonates and sulfates of soda were reported under development in Washington, but no commercial output has been made as yet.

The greater part of the production of sodium borates is from the kernite ($Na_2B_4O_7 \cdot 4H_2O$) deposits of the Pacific Coast Borax Co. near Mojave, Kern County, Calif. However, as previously noted, borax also is produced in California in conjunction with other sodium salts from Searles Lake by the American Potash & Chemical Corporation and the West End Chemical Co.; it is also recovered from Owens Lake by the Pacific Alkali Co. at Bartlett. In the latter part of 1938 the Stanford Investment Co., Los Angeles, Calif., started mining borate

159434—39——88

Digitized by Google

minerals on Government lands near Tonopah, Esmeralda County, Nev., but no shipments were made. Exports of borax, after rising rapidly from 87,677 short tons in 1933 to a peak of 154,052 tons in 1937, dropped in 1938 to 77,519 tons valued at $2,642,446. This represents a reduction of 76,533 tons and accounts for 55 percent of the decrease in total shipments. The apparent quantity of borax available for domestic consumption (after deducting exports) dropped 31 percent but was greater than for any year prior to 1935.

## DEEPER DRILLING AT SEARLES LAKE

Hitherto exploration of the remarkable saline deposits of Searles Lake has been confined to wells not more than 150 feet deep, and drilling has been stopped usually as soon as mud appeared in the cores or cuttings. Not long ago, however, William F. Foshag, curator of mineralogy for the Smithsonian Institution, Washington, D. C., suggested going deeper, and, with the cooperation of W. A. Gale, director of research of the American Potash & Chemical Corporation, holes were driven to the 300-foot level.

At present Searles Lake has the general appearance of a frozen waste, the dried salts forming an icelike crust so solid that an automobile can be driven over it. Only occasionally does the water level (brine) rise to the surface, but the porous salts usually are brine-soaked a foot or two below the surface, and wells 10 to 20 feet deep yield adequate flowage for pumping to the refineries. The top crust is chiefly common salt (sodium chloride) and varies in thickness, averaging perhaps 10 feet. Underlying this crust and extending to depths of 75 to 200 feet is a relatively solid mass of intermingled saline minerals that vary greatly in composition both horizontally and vertically. At greater depths, however, the proportion of bicarbonate increases, and just above the top of the clay is a thin bed of salts rich in borax which is disseminated irregularly higher up.

The latest prospect holes reveal that reefs of dry salts extend below and are interstratified with the clay. Dr. Foshag has found from his examination of the cores that at depth these reefs are almost pure bicarbonate of soda. Although common enough as a medicinal, household, and industrial chemical, this compound has never before been known to occur naturally as a mineral. At intermediate depths he has identified another mineral that likewise has been known heretofore only as an artificial chemical compound. This is a double sulfate and carbonate of soda termed "burkeite."

Although the quantity of salts in the upper layers of this deposit is more than ample to supply the needs of commercial operations for many years, the discovery of these enormous additional beds is of much scientific interest.

Retail sales of jewelry in 1938 totaled about $276,000,000, or 11.5 percent below the 1937 sales ($312,000,000) and slightly below those of 1936 ($280,000,000). Diamond rings, watches, and gold jewelry were the principal sales items. January was a fair month, February and March were poor, and May and June were better; July witnessed a slump from which a slight improvement was noted each month until the usual marked increase in December (sales in that month usually make up 25 percent of the year's sales). Although the Christmas sales of 1938 were almost as good as those of 1937, it was disappointing that no one of the later months of 1938 exceeded those of 1937 when, it will be remembered, trade was poor. The wholesalers' jewelry sales, in comparison, were 27 to 29 percent lower than those of 1937; consequently retailers' stocks at the end of 1938 were smaller than at the end of 1937. The demand for popular-price articles was better than for items in the higher price brackets, and the sales of costume jewelry were remarkably large.

*Fashions in jewels.*—Jewels continue to be worn in almost barbaric profusion, with large stones prominent. Gold, often in two colors, is even being worn in the evening and continues its gain at the expense of platinum. Silver jewelry also became popular in 1938. The motifs range from Hindu and Persian to French of the times of Louis XIV and of the late Directoire, as well as Victorian types and those of the nineties of the last century. Massive gold chains with pendant watches, crosses, or cameos, imposing necklaces and dog collars, and jeweled flowers and leaves are popular; jeweled hair ornaments and earrings, either long pendants or set close to the lobe of the ear, are imperative with the present coiffures. Tiaras are again worn, particularly in England. Much of the jewelry is flexible, permitting the stones to move with the wearer's movements. The ensemble is as much in vogue in jewels as in dress accessories. Costume jewelry ("junk" jewelry in the trade) is sold in quantity and may foster a love

[1] One of the consulting engineers, Bureau of Mines.

Digitized by Google

for the real article. The demand for colored stones grows, such jewelry requiring the use of countless small diamonds set pavé for contrast. The finer gems—diamonds, including "fancies," ruby, emerald, and sapphire—hold the center of the stage, but topaz and aquamarine are extremely popular, and the use of turquoise, moonstone, and amethyst and a host of other colored stones is increasing. Men are wearing more jewelry, featuring particularly star sapphire and ruby, cat's-eye, and the quartz gems.

*Domestic production.*—From the peak of American gem-stone production of $534,280 in 1909 the industry dwindled until 1934, when the value of the production was only about $3,000. Since then it has increased appreciably, and in 1938 the total output was perhaps $127,000; as the production is largely by individuals or partnerships and there is no canvass, exact figures are not available. The revival of the industry is due to two factors—the desire of tourists to purchase souvenirs and the increasing use of a variety of colored stones in jewelry. The demand by jewelers for American tourmaline, kunzite, and turquoise is insistent; the sales of Navajo turquoise-silver jewelry, for example, probably exceeded those of 1937 by some 15 percent.

In the Northwest and especially in Oregon, according to correspondence with H. C. Dake, are a large number of collectors of agate and other quartz minerals, many of whom are amateur lapidaries, while others send their "finds" to professional lapidaries, some 50 in number. It is estimated that in 1938 in Oregon material valued at $210,000 was collected; in Washington, $85,000; in Idaho, $35,000; and in Wyoming (largely moss agate) $8,000—a total of $338,000. Most of these agates remain in private collections, although it is believed that about one-fourth of the amount is sold to tourists. Turquoise valued at almost $30,000 was produced in 1938, and the United States is again the most important producer of this gem. Nevada produced over 80 percent of the total, Colorado 15 percent, and Arizona a small quantity. Southeastern Montana, as usual, produced a large amount of moss agate from the Yellowstone Valley which found a ready market among tourists. Scott's Rose Quartz Co., Custer, S. Dak., produced about 1,000 pounds of rose quartz. Considerable kunzite and a little tourmaline was produced by one firm in San Diego County, Calif.

William O. Vanderburg lists 39 turquoise mines in Nevada; in part he says:

> The production of turquoise and turquoise matrix in Nevada for 1938 was approximately 8,000 pounds, varying in value from $0.50 per pound for off-color and inferior grade material to $40 per pound for the finest quality. Due to the fact that the bulk of the production is made by individuals and firms who do their own cutting and polishing it is difficult to arrive at the value of the crude turquoise. Probably an average value for the crude material would be about $3.00 per pound. After the gems are cut and polished, sorted, and graded according to quality the value increases considerably.
>
> As a result of the increased demand for turquoise a number of deposits have been discovered in Nevada within the last 2 or 3 years. One of the notable features of turquoise mining in Nevada during the year was the shift in the bulk of the production from the deposits in Nye and Esmeralda Counties, centering around Tonopah, to the recently discovered deposits in Lander County with Battle Mountain and Austin as the producing centers. The principal producers of turquoise in Nevada in 1938 were the Burnham Bros., Guy Grannis, W. F. Godber (Western Gem & Jewel Co., Los Angeles), and Geo. McGinnis and associates, all of whom operated properties near Hickerson Summit, Lander County;

Digitized by Google

Lee F. Hand and C. T. Johnson, owners of turquoise properties in the Royston and Crow Springs districts, Nye and Esmeralda Counties; Ed. C. Smith, who operated the Smith mine, Cortez district, Lander County; D. J. Wilson (American Gem Co., Los Angeles), who worked a deposit in Copper Basin, northern Lander County, under a lease agreement with the Copper Canyon Mining Co.; and W. F. Godber, owner of the Reik mine in the Candelaria district, Mineral County.

The turquoise mined in Nevada varies considerably in color, ranging from green, blue-green, and various shades of blue to nearly white. The best quality is a rich blue color. Off-color material is hard to dispose of in the United States, although small lots of the inferior grades of turquoise have in recent years been sold to Germany. Turquoise matrix has an established popularity with the tourist trade, and some of its numerous varieties are characteristic of certain properties such as "black", "spider web", "gold", "brown", or "pinto matrix".

The turquoise mines in Nevada are not operated continuously; activity is restricted to the summer months, and the degree of activity is dependent on the demands of the jewelry trade. One of the most pronounced trends in Nevada turquoise mining in recent years is the tendency of the cutting establishments to acquire their own mines. Only a few years ago the principal outlets for crude turquoise were traders who made annual trips through the State, bartering articles of Indian craftsmanship for the crude turquoise, and in turn trading it to the Indians of the southwest.

The mining of turquoise is popular with miners of limited means because a minimum of equipment is necessary.

The discovery of emerald at Rye Patch, Pershing County, Nev., was widely heralded early in 1939 as the first deposit of emerald found in the United States, although deposits of the gem have long been known in North Carolina and other Eastern States. The Nevada emerald occurs as unusually deep-color marginal parts of beryl crystals in a pegmatite that intrudes limestone. The deep-color material makes up a relatively small part of the beryl, and most of it is flawed and not transparent; in consequence, the commercial importance of the find is doubtful. An abandoned emerald mine 15 miles south of Spruce Pine, N. C., was reopened early in 1938. North Carolina produced a little emerald matrix.

Near Hot Springs, Ark., there are at least seven producers of rock crystal, and these and others sell the product.

Among the other gem stones produced in the United States in 1938 were agatized wood (private lands surrounding Petrified National Monument, Ariz.); amazon stone (Teller County, Colo.); amethyst (North Carolina; and Larimer County, Colo.); aquamarine (North Carolina and Chaffee and Park Counties, Colo.); chrysoberyl (Jefferson County, Colo.); garnet (North Carolina; Custer, Chaffee, and Jefferson Counties, Colo.; and Emerald Creek, Idaho); fire opal (Owyhee County, Idaho); phenacite (Chaffee County, Colo.); ruby (North Carolina and Georgia); smoky quartz (North Carolina); and topaz (El Dorado County, Calif.; Thomas Range, Utah; and Teller and Park Counties, Colo.).

Charles H. Carpp and J. W. Kaiser operated the property of the American Gem Mining Syndicate, near Phillipsburg, Mont., in 1938. They produced 9,480 ounces of industrial sapphire valued at about $11,000. The Rocky Mountain Alabaster Co., Fort Collins, Colo., quarried about 50 tons of alabaster in 1938. Some Iceland spar of optical grade was produced in California.

*Imports.*—According to the Bureau of Foreign and Domestic Commerce, imports of precious and imitation stones (exclusive of industrial diamonds) into the United States in 1938 totaled $28,304,956, a

Digitized by Google

decrease of 36 percent from 1937. Details are shown in the following table.

| | Carats | Value |
|---|---|---|
| Diamonds: | | |
| Rough, uncut, duty free | 91, 515 | $7, 077, 159 |
| Cut, but not set, dutiable | 330, 925 | 17, 016, 842 |
| Pearls, not strung or set, dutiable | | 470, 304 |
| Other precious stones: | | |
| Rough, uncut, free | | 116, 924 |
| Cut, but not set, dutiable | | 1, 698, 916 |
| Imitation, except opaque, dutiable | | 1, 762, 458 |
| Imitation, opaque, including imitation pearls, dutiable | | 18, 896 |
| Marcasites, dutiable | | 143, 457 |

*Tariffs.*—There were few important changes in tariffs during the year. In the United States, under the provisions of the Czechoslovak Trade Agreement negotiated last spring, the duties on Czechoslovak imitation stones in the various brackets were reduced as much as 50 percent. Czechoslovakia was by far the chief source of such imitation stones, particularly rhinestones. The effect of the agreement was nullified when Germany occupied Czechoslovakia. Germany made barter agreements with some of the diamond-producing countries, without impressive results, however. A trade agreement with Brazil was canceled, and some of the others are stated to be inoperative.

*Trade terms and judicial proceedings.*—The Federal Trade Commission on March 18, 1938, issued its Trade Practice Rules for the Wholesale Jewelry Industry, a recodification of unfair methods of competition and other illegal practices in the trade. The use of the word "perfect" in describing a gem that under a 10-power loupe shows any imperfection is unfair practice; "perfectly cut" is not to be used to deceive the purchaser; the use of "diamond," "ruby," or other names is to be confined to these mineral species alone; "real," "genuine," and "natural" cannot be applied to synthetic or imitation stones; "blue white" cannot be applied to a diamond if at all off-color; articles must be as advertised; the adjective "synthetic" must be confined to synthetic stones. The Federal Trade Commission during the year issued a number of cease and desist orders against firms not living up to its trade rules.

In the fall, the Department of Commerce released texts of two commercial standards, covering gold and platinum.

The Jewelers Vigilance Committee continued its good work against shortcomings of the less ethical members of the trade; as for example, against a store that sold 0.72-carat diamonds as 1-carat solitaires. But even they are unable to do away wholly with the occasional switching of pieces of glass for diamonds, a case of this kind having occurred in Baltimore a few months ago.

*Exhibits.*—At the New York World's Fair jewels will be among the most attractive exhibits. In the House of Jewels, five of the leading New York jewlers will show their most beautiful jewelry, and De Beers & Associated Producing Cos. and the Diamond Corporation will exhibit rough and cut diamonds, an exhibit valued at over $5,000,000. In the Belgian pavilion, besides cut diamonds worth several millions, the art of diamond cutting will be shown. In Iraq's exhibit, goldsmiths from Baghdad will ply their ancient art. The Crown of the Andes, set with innumerable Colombian emeralds, is to be on exhibition. Boart Products, Ltd., is to have in the Hall of Mining and Metallurgy

Digitized by Google

an instructive exhibit showing the industrial uses of diamonds. These exhibits should strengthen the gem consciousness of the American people and promote jewelry sales.

## DIAMOND

The improvement in the diamond industry, which had continued for over 5 years, ended in September 1937; and 1938—with its wars, changes in the political map of Europe, and financial depression—was a poor year, as was to be expected with an industry that feeds on prosperity. The small demand and a large mine output increased stocks of rough diamonds for the first time in 6 years, although stocks of cut stones in the hands of cutters and retailers are not large. Prices of rough were firm, and those of cut diamonds tended to advance.

*Share dealings.*—The shares of diamond-mining companies listed on the London Stock Exchange had a relatively narrow market in 1938. Off to a good start, by January 15 quotations began to slip, and, except for a short rally in April, the decline continued until mid-July, after which prices strengthened for 2 months. The Czechoslovak crisis affected the market adversely, but this was followed by a sharp rise in October. For the rest of the year the market was inclined to be weak. The loss for the year was about 25 percent, the quotations of five representative stocks at the year end being 37 percent of their high (1927) and 370 percent of their low (1932). Of the more important stocks, 12 paid dividends.

*Market.*—The Diamond Trading Co. sold rough diamonds valued at about £4,000,000, only 44 percent of the sales of 1937. Sales in the third quarter were quite satisfactory, those of the first and fourth quarters fair, and those of the second quarter small. Good-quality large stones are still scarce.

Sales of polished stones were only about one-half those of 1937, the principal demand being for small goods and most of them of mediocre quality. June and July were the best months, as the Czechoslovak crisis interfered with the usual purchases for the Christmas trade. The United States, Argentina, India, and (early in the year) southeastern Europe were large purchasers.

As is usual in years of political crises, investment buying increased the sale of large stones, while the mode for pavé jewelry promoted the demand for small stones. Sales of industrial stones were large.

*Growth of diamond-cutting industry.*—Diamond cutting originated in India, where diamonds first were discovered, certainly well over a thousand years ago, and to Hindu lapidaries we owe the two basic principles of the art—the wheel and the use of diamond dust. Indeed, it was not until early in the seventeenth century that Europe wrested the cutting supremacy from India and its ally, Borneo, now for the past 2 centuries the most important of the eastern cutting countries. The Hindu cut too crudely for European taste, in part prompting the growth of the European industry. By the sixteenth century European artisans surpassed their eastern confreres in skill and were in demand at eastern courts.

The art was transmitted from India to Constantinople and later to Venice. Cut stones appeared in Europe between the eighth and thirteenth centuries. The art reached northern Europe at the turn of the fourteenth century, first at Nuremberg and Paris, and probably

Digitized by Google

Bruges only slightly later. Religious persecution drove the cutters from Bruges to Antwerp and soon thereafter to Amsterdam, later the asylum of persecuted Jews from Portugal, Spain, and Poland. Excluded from the guilds, they sought the free professions, among them diamond cutting. Diamond cutting appeared on the Western Continent in Brazil in 1802, and in the late sixties of the last century a cutting industry sprang up in the United States, small in roster but renowned for its superior product. The Government-subsidized South African industry, started in 1928, thrived for only 5 or 6 years.

The art of cutting has made steady improvement, slow at first but thereafter marked, particularly in our generation. Hindus, Venetians,

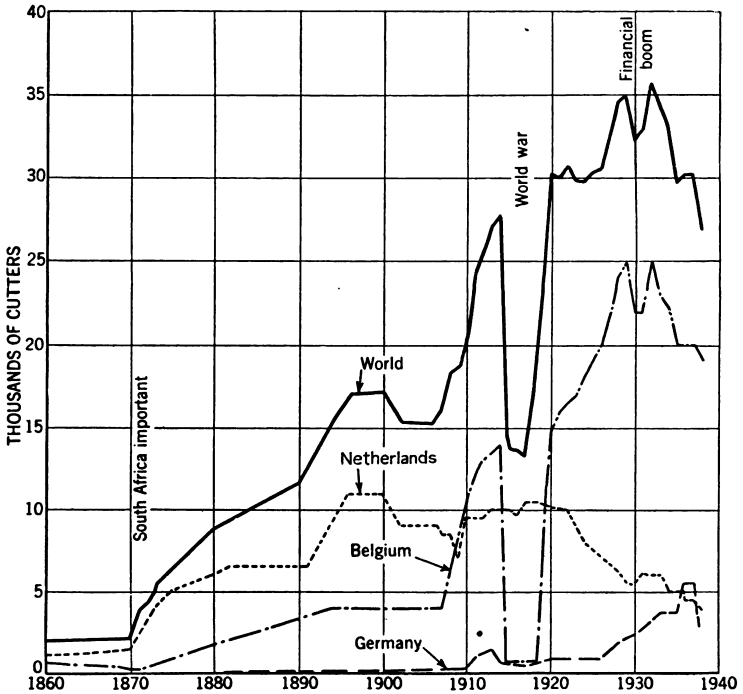

FIGURE 1.—Approximate number of diamond cutters in Belgium, Germany, Netherlands, and the world, 1860–1938.

Flemish people, both Catholic and Protestant, Netherlanders, Jews, and Americans have all made notable contributions to the craft.

An adequate supply of rough diamonds is necessary to the growth of the art. The Indian mines created the ancient industry of India and with their decline the industry died. Cutting in Borneo was fed first from the local mines, but now is supplemented by imported South African rough. Lisbon was an important cutting center while Portugal controlled the India trade, and the dominant position of the Netherlands as a cutting center was due first to her Indian trade and later to her monopoly of Brazilian rough. On the other hand, the French industry established by Cardinal Mazarin about 1650 starved to death owing to the lack of an adequate supply of rough diamonds. With the rough market centered in London, rough is now available to all cutters.

Digitized by Google

Bruges was the dominant center during most of the fifteenth century, Antwerp from 1483 to 1585, and then Amsterdam for over 3 centuries. In 1909 Antwerp regained the lead and has held it since, except for the World War period. During the past decade the growth of the craft in Germany has been phenomenal. That country, like Belgium, cuts small rough, while the Netherlands specializes in large.

During the financial boom of a decade ago, the industry became geared to prosperous times and since 1929 has been markedly overstaffed.

An ancient industry, the secrets of which were carefully guarded till 60 years ago; once a home industry, taught by father to son, it is now carried on in large factories. Started as a family trade, it has become big business. Sixty-five years ago the prince of artisans, the diamond cutter today, due to the unjustified growth of his craft, receives an indifferent and desultory wage. Unless great prosperity awaits in the near future, many a diamond cutter must seek employment in more profitable industries.

In 1500 A. D. there were some 600 cutters (India, 500; Europe, 100): 1660, 1,400 (India-Borneo, 400; Europe, 1,000): 1700, 950 (India-Borneo, 350; Europe, 600): 1770, 1,400 (India-Borneo, 300; Europe, 1,100); and in 1810 but 700, owing to the Napoleonic wars (India-Borneo, 300; Europe, 400). The growth of the industry since 1860 is shown in figure 1.

*Cutting in 1938.*—The diamond-cutting industry had a poor year, marked by little profit for the "masters" and increased unemployment among the men. Many of the latter were absorbed by other industries. Although the Belgian and Netherland centers lost ground, the German industry, which during the past decade has had such a phenomenal growth, suffered most severely.

*Imports.*—Diamond imports into the United States in 1938, by countries, were as follows:

*Diamonds imported into the United States in 1938, by countries* [1]

[Exclusive of industrial diamonds]

| Country | Rough, or uncut | | | Cut, but not set | | |
|---|---|---|---|---|---|---|
| | Carats | Value | | Carats | Value | |

*World production.*—World production of diamonds (gem and industrial) in 1938 approximated 11,755,200 carats (2.351 tons) worth about $43,000,000. Compared with 1937 this is an increase of 22.5 percent by weight, without much variation in value, as the increase was largely in low-price industrials. As only Dutoitspan and Bulfontein of the South African pipe mines were operated, the alluvial mines produced 91.5 percent by weight and 70 percent of the value. The British Empire produced 31 percent by weight and 69 percent of the value. Of the total production, less than one-fourth by weight were gem stones.

The following table gives, as accurately as available statistics permit, world diamond production for the past 5 years:

*World production of diamonds, 1934–38, by countries, in carats*

[Including industrial diamonds]

| Country | 1934 | 1935 | 1936 | 1937 | 1938 |
|---|---|---|---|---|---|

[1] Estimated.
[2] Exports.
[3] Includes a small quantity of diamonds recovered from retreatment of tailings.
[4] 1934: Netherland India (Borneo), India, Australia (New South Wales), Rhodesia, Nigeria, United States (California), and Venezuela; 1935: Netherland India (Borneo), India, Nigeria, and Venezuela; 1936: Netherland India (Borneo), India, Rhodesia, United States (California), and Venezuela; 1937: Netherland India (Borneo), India, Australia (New South Wales), Liberia, Venezuela, and Rhodesia; 1938: U. S. S. R., India, Borneo, New South Wales, Venezuela.

The increased production in 1938 compared to that of 1937 was due largely to an unusually large production of industrial stones by the Belgian Congo. South Africa increased its production about 20 percent, and the small outputs of French Africa and of miscellaneous sources increased markedly. The production of South-West Africa decreased about 26 percent and that of Gold Coast 17 percent.

*Industrial diamonds.*—More diamonds were used industrially in 1938 than ever before, although, as the proportion of crushing bort used increased, the dollar sales value probably was somewhat less than in 1937. The increase was due largely to the world-wide armament race and the need of a superabrasive to cut and shape hard alloy steels, as well as to the diversified use of diamond grains bonded in plastics and powdered metals. Over two-thirds, by weight, of the world diamond output is used in industry, mainly in the United States, Great Britain, Canada, Germany, and the U. S. S. R.

Digitized by Google

The demand for industrial stones was strong throughout 1938. As the finer stones are scarce, industry was forced to use the smaller stones and those of mediocre quality more and more. Carbonado (the Brazilian "black diamond") is now selling at a price that for certain purposes renders its use attractive. Prices were firm, with an upward tendency.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

*Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1934–38* [1]

| Year | Carats | Value | | Year | Carats | Value | |
|---|---|---|---|---|---|---|---|
| | | Total | Per carat | | | Total | Per carat |

## EMERALD, RUBY, AND SAPPHIRE

For the third successive year the lavish use of colored stones in jewelry depleted the store obtainable from old jewelry and brought nearer the time when the colored-gem mines will have to increase their scale of operation or a shortage will result. Barring a world war or a financial cataclysm prices must rise.

The Government-owned Muzo emerald mine, Colombia, was closed at least most of the year and early in 1939 was to be leased to private parties. The Government gives, rather naively, the theft of the better stones by the miners as the reason for the proposed change in management. The Chivor Emerald Mines, Colombia, operated on a restricted scale in 1938. The Bank of the Republic is said to have 24,000 carats of uncut emeralds stored in its vaults. The Cobra Emerald Mine, South Africa, in 1937 was operated by the African & European Investment Co. at a small profit. The official figures of the value of emerald produced in South Africa were £6,082 in 1936 and £10,838 in 1937. Victor Leinz and O. H. Leonardos report the occurrence of emeralds in detrital deposits in the State of Goyaz, Brazil, 20 miles southeast of the city of Goyaz. The stones are of good color but are badly flawed and lack transparency. The geological occurrence suggests affiliation with occurrences in the U. S. S. R., Egypt, and North Carolina—mica schists cut by pegmatites. The emerald mine at Habachtal (former Austria) is now in German territory.

In 1937 Burma produced 157,308 carats of rubies valued at £6,841 (20 cents a carat). Its rubies and byproduct sapphires were valued at £7,069 as opposed to £7,319 in 1936. Burmese miners in Cambodia produced a few rubies, sapphires, and zircons at the alluvial mines at Païlin and at Bo-Keo. The 1936 value was 1,880 piasters, three-fourths from the first locality and one-fourth from the second. Production, in carats, has been as follows: 1934, 450; 1935, 312; and 1936, 104.

India in 1937 produced 22,736 carats of sapphire, largely from Kashmir. The value as officially given is £1,682 in 1936 and £41 in

Digitized by Google

1937. The larger part of the Kashmir production is understood to be only usable industrially.

Sapphires valued at £1,410 were sold in the Anakie (Queensland) field in 1937 (£2,030 in 1936). Twenty-five men were engaged in mining, largely around Ruby and Sapphire, although some of them were attempting to locate new leads in the surrounding country. First blues, only a small percentage of the production, were in demand, but yellows and greens were difficult to sell. The Miners' Association sold largely in France, although a few fine stones were disposed of in America. Queensland produced gems, largely sapphires, from 1860 to 1937, inclusive, worth £643,156, the years of important production being 1907 to 1925.

The special committee appointed by the Government of Ceylon to investigate the gem-mining industry at first decided to establish a Government cutting works and a sales room at Colombo but finally recommended that the miners bring their stones to small depots where they could obtain the best current prices. The committee recommended further that an up-to-date map of the gemmiferous area be made, as it believes much illicit mining is being carried on and that there are several unexplored areas in Ceylon where gems may be found. Whether the central depots will be advantageous to the trade, time alone can tell. The Government could perhaps spend its efforts more advantageously in preventing unscrupulous merchants from selling synthetics and imitations as genuine stones.

## LESSER GEMS

The all-time opal production of New South Wales is valued at £1,622,795, although for the 10 years, 1928–37, the average yearly production has been but £4,803. The 1936 production was valued at £6,110 and that of 1937 at £3,357. In the latter year over 97 percent came from Lightning Ridge, Grawin and White Cliffs supplying the remainder. The total opal production of Queensland from 1860 to 1937 is valued at £187,745, the big production being in the last 8 years of the nineties. In 1936 the production was only worth £150 and in 1937 had shrunk to £16. This came from Sheep Station Creek in the Quilpie district, where four men prospected part of the year. South Australia had sold opal to the value of £160,158 from 1916 to 1937. In 1937, £11,887 worth of opal was marketed, the most satisfactory year since 1920. The demand was better than usual, and hence mining was more active. Coober Pedy was the principal source; but two smaller fields, Mintabic and Andamooka, also produced. Opal artifacts and jade and crystal beads were found in a cave near Nakuru, Kenya, by Dr. L. S. B. Leakey, the distinguished archaeologist. The objects are believed to date from about 4,000 B. C. Dr. Leakey believes there were important opal mines in the vicinity.

In 1937 about 40 men gophered turquoise stringers at Nishapur, Iran. The owners, an Iranian mining company in Meshed, plan to drive a large tunnel 200 to 300 feet beneath the deepest old workings, which in turn are several hundred feet beneath the surface. The company cuts and mounts the turquoise in a small shop at Meshed. The same company also mines and sells salt; according to a letter from Lester S. Thompson, to increase the sale of the latter, a cheap

Digitized by Google

turquoise ring is concealed in every five-hundredth 1-kilo package of table salt sold. A little turquoise (20 oz. worth £8 in 1936, none in 1937) is produced from time to time in the Brisbane district, Queensland.

The Afghanistan lapis lazuli contact-metamorphic deposits are worked by long tunnels whose sides are badly smoked, the rock having been broken by fire setting. It is believed there has been no mining for 10 years, the lapis lazuli sold coming from stocks on hand. Ernest F. Fox states that the best goes to Kabul, where it is cut.

In 1937, 2,952 cwt. of jadeite were produced in Burma, nearly double the previous year's production, although the value (£13,030) was lower (£13,412).

Burma also produced amber valued at £668 (£409 in 1936). Recent production of amber in Germany was, 1935, 112 metric tons; 1936, 332 metric tons; and 1937, 328 metric tons.

Vesuvianite of fine gem quality is produced to a limited extent at Laurel, Quebec.

Considerable amounts of jet are produced in the Province of Kompong-Thom, Cambodia (1934, 13,000 kilos; 1935, 24,000 kilos; and 1936, 24,270 kilos).

The United States annually imports from Brazil 5 to 6 tons of unusually fine quartz crystals absolutely essential in radios and in telephonic, telegraphic, and optical apparatus. Even if the finest crystals are used, the finished plates represent but a twentieth of the original. Minas Geraes exports its rock crystal to the United States, Germany, and Japan. Mining is primitive and rarely is carried to any considerable depth. Recently a fine rock crystal from Minas Geraes, Brazil, was sent to this country. It weighed 63 pounds and was sold for over $1,100, or about $18 per pound.

Amethysts occur in seams in trap rock near Scott's Bay, Nova Scotia, on the Bay of Fundy. The winter's frost each year forms new outcrops. Some of the amethysts are cut in Europe, returned to Nova Scotia, set in lockets or rings, and, together with rough crystals, sold to tourists. The trade has increased greatly in the last 6 or 7 years.

Several tons of rose quartz from pegmatic dikes in Minas Geraes, Brazil, are sold annually. Japan, China, and Germany are the principal markets, the best grades bringing $500 to $600 per metric ton. The State of Hyderabad, India, has widely distributed deposits of agate, plasma, and bloodstone.

The Iceland spar deposit at Hegustader, Iceland, is still operated as a Government monopoly.

As a result of 1938 political changes, the well-known Bohemian garnet localities and the Czerwenitza opal locality became German territory. It is understood that further working of the Jordansmühl (Silesia) nephrite deposits is to be regulated by the German Government.

In 1936, 13 companies were mining precious stones in Madagascar, although the production only was worth some $21,000. In 1936, 6.6 kilos of beryl, tourmaline, and kunzite were exported (4.5 kilos in 1935 and 9 kilos in 1934) and 31 kilos of feldspar and quartz gems, garnets, and similar stones (16 kilos in 1935, 23 in 1934). In addition much greater weights of industrial stones were exported. The demand is, however, so irregular that exports for a single year mean little.

Digitized by Google

The mines are small units, and the use of explosives is avoided lest the gems be ruined.

South-West Africa in 1937 produced 46.765 kilos of precious stones, largely tourmaline. Sales, largely to Germany, were, however, 688.987 kilos. In the first 9 months of 1938, 110.563 kilos were sold for £1,182. The stones included aquamarine, tourmaline, topaz, rose quartz, and chalcedony.

Brazil is the most important producer of the lesser gems, but figures on its 1938 production are not at hand.

## SYNTHETICS

The Gemmological Institute of America in a study of synthetic emeralds finds the best method of distinguishing synthetics from real is the presence of irregular cracklike or wisplike markings in the synthetics, imperfections markedly different from the blemishes of emeralds.[2]

The Russian Precious Stone Trust is now making synthetics in its Leningrad laboratory, several of which, a sapphire of 292 carats and a ruby of 250 carats, are sizable.

The I. G. Farben-Industrie has a large synthetic-gem plant at Bitterfeld, Germany, which produces several thousand carats of synthetics a day. Some are sent to Oberstein for cutting, and others are used as jewels for watches and bearings for precision instruments.

## CARBON DIOXIDE

Continued progress was made in the production and use of solid and liquid carbon dioxide in 1938. The volume of business was approximately the same as in 1937, when the output (Census figures) of dry ice was 156,609 tons, valued at $4,618,937, and of liquid or gaseous $CO_2$ (including about 8,500 tons piped to dry-ice plants) 50,358 tons, worth $4,939,508. No radical new uses for either liquid or solid carbon dioxide were developed in 1938, but the use of the latter product for refrigeration continued to expand.

Natural-gas wells suitable for producing solid carbon dioxide are found in several States, and natural dry-ice plants have been built in California, Colorado, New Mexico, Utah, and Washington. Nevertheless, natural gas is a very small factor in the present-day volume of either liquid or solid carbon dioxide produced domestically, because the wells are so far from the population centers that consume the bulk of the products. As evaporation of solid carbon dioxide commences the moment it is made, the economics of distribution of this product differs from that of most commodities. Not only do freight charges add to the cost of distant shipment, but also the volume of the product diminishes more or less inversely with the time of exposure in transit or warehouse. Evaporation losses on large shipments are proportionately less than on smaller lots, but it has never proved economical to transport carbon dioxide to far-away markets. Byproduct gas from limekilns, cement mills, and metallurgical plants is more important than natural gas, largely because such plants are more likely to be situated in or near large cities or towns that afford markets. Over half the liquid carbon dioxide manufactured is made from the combustion of coke, coal, oil, and natural gas.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Digitized by Google

Geographic location is not the only economic factor. Even by-product gas has comparatively little value unless waste power also is available. A properly designed combustion unit employing coke consumes virtually all the power developed by combustion to purify and compress the liberated gas to liquid and solid forms. However, the utilization of byproduct gas, particularly in localities where surplus power or cheap electricity is available, has been facilitated by improvements in methods of absorption and purification. As stated in Minerals Yearbook, 1938, fully 20,000,000 tons of $CO_2$ are liberated in a normal year at American cement and lime-burning plants alone, and there is little prospect of all this gas being captured successfully and sold at a profit. Both soda and potash solutions are used for absorption and purification of raw gases, and under certain conditions even better results are obtainable by using triethanolamine. The latter absorbent is the basis of the Girbotol process (United States Patent reissue 18958), which protects the use of aliphatic amines for the separation and recovery of acidic gases from gas mixtures. The cycle is identical with the orthodox potassium carbonate cycle, but the reagents have more capacity for carbon dioxide than does inorganic carbonate; moreover, they are more reactive and are easily regenerated. A letter from the Girdler Corporation, Louisville, Ky., states that the Girbotol process is used for the recovery of $CO_2$ in plants having a total installed capacity of 120 tons of carbon dioxide per day. This process is also used to remove carbon dioxide from gas mixtures, and in many plants the $CO_2$ is not recovered commercially. In fact, the quantity so wasted is considerably greater than the total capacity of plants that recover it commercially.

According to H. J. Duncan, of the Geological Survey, the Northwest Natural Gas Corporation at Klickitat, Wash., which has 13 wells producing from depths of 50 to 500 feet, is deepening one of its wells in the hope of obtaining an additional supply of gas. The plant now has a daily capacity of 6 tons, which retails at 3 cents per pound. Liquid carbon dioxide is bottled for soda-fountain consumption, and the company also has a contract to supply a large chain of stores with carbonated water. No treatment is necessary to purify the gas which needs only to be separated from entrained water.

According to State mineralogist Walter W. Bradley,[2] natural carbon dioxide gas was first obtained commercially in California in 1894 at the Santa Isabel shaft of the New Almaden quicksilver mine, Santa Clara County, where a drift on the 575 level was bulkheaded and the gas drawn out through a pipe, compressed in cylinders, and used to make soda water. Since 1933 carbon dioxide gas, produced from wells drilled on the edge of Salton Sea near Niland, Imperial County, has been converted into dry ice and shipped by truck to Los Angeles. The plant has a daily capacity of 10 tons but apparently has never operated at over half this rate.

In Germany dry ice is reported as being used successfully to preserve bakery products in transport or storage.[3] According to a later report from the office of the American commercial attaché in The Hague, dry ice is used quite generally in the Netherlands by large retailers and chain stores to protect confectionery, cakes, pastry, and bread-

Digitized by Google

stuffs, as well as ice cream. It is also used in household refrigerators. The use of dry ice in bakeries was introduced about 2 years ago because the Dutch Government passed a law prohibiting night work, thus preventing delivery of fresh bread in the early morning.

Liquid carbon dioxide derived from natural springs in Ecuador has been offered for sale in Panama.

Experiments at the University of Minnesota on the use of $CO_2$ for the preservation of certain fruits have passed the experimental stage, and for the last 3 years Minnesota growers have been shipping and selling strawberries and raspberries to dealers in surrounding States with considerable success. The berries are reported to be firmer in texture, brighter in color, and far freer from mold than those not gassed.[4] Reviving the idea of stimulating plant growth in greenhouses, and possibly in connection with newly developed methods of soilless cultivation, a University of Colorado professor [5] has called attention to the possibility of piping the gas from natural wells. He suggests that it may even be possible to flood open fields with it. The vast quantities of carbon dioxide available are indicated by the measurement of one gas well in Mexico that discharges 150,000,000 cubic feet of $CO_2$ daily, enough to make 9,000 tons of dry ice. The pressures at some wells approach 1,000 pounds per square inch. Earl S. Johnson,[6] of the Smithsonian Institution, recently has pointed out that increased light intensity as a means of forcing plants to grow faster is only effective up to a certain point because the carbon dioxide naturally present in air does not equal that required during accelerated photosynthesis. He states that the practical application of aerial fertilization with carbon dioxide and the source of supply of carbon dioxide in amounts adequate for field work are still unsolved problems, but that application of carbon dioxide to greenhouse culture appears more promising.

Summarizing the international situation, the foreign correspondent of a Canadian chemical journal [7] observes that the solid carbon dioxide business in the United States and Canada advanced to a certain point and then hesitated owing to complicated economic reasons, whereas in England where the application of refrigeration was less advanced the dry-ice business had a better chance to develop. A substantial tonnage of English $CO_2$ has been used in carrying fish to London from Scotland and on other overnight hauls for which dry ice is especially well-suited. On the other hand, little progress has been made in France and Germany. Norway, however, seems to have the most ambitious plans; there may be quite a development in shipping about Europe fish frozen with carbon dioxide.

## GRAPHITE

Domestic graphite mining, which has been virtually dormant for several years, was animated in 1938 with the completion of a new plant at Morristown, N. Y., by the Long Valley Ore Co. The rock, which is said to run 20 to 25 percent graphite, is ground in a Hardinge ball mill and concentrated by flotation, the rougher concentrates being cleaned in a second battery of cells. The concentrates from the

Digitized by Google

cleaners are thickened to about 20 percent moisture, filtered, and dried. The product runs 85 to 90 percent carbon and is as pure as some of the Ceylon graphites. It is an excellent foundry facing and is also suitable for battery manufacture. A fair proportion of the material is flake, but the flakes are small and apparently unsuitable for crucible making. No detrimental impurities are found in the gangue, and the concentrates are free from all metallic elements except the usual percentage of iron oxide. The capacity of the plant is 15 tons a day but can be increased if demand warrants. The various California producers were idle in 1938, and the Western Graphite Co., Los Angeles, Calif., was dissolved as of December 1. The Graphite Corporation has announced its intention to open a new plant at Shelbyville, Tenn. At Clarkesville, Ga., the Southern Mining & Milling Co. increased its recovery of graphite as a joint product of its kyanite operations. The Texas Graphite Co., Llano, Tex., which was reorganized in 1936, began operations in 1937 and shipped a small amount of crystalline graphite for foundry facings in that year. No production was reported by the company during 1938, but operations may be resumed in 1939. Fully a dozen other companies are carried on the Bureau of Mines records as possible producers of crystalline graphite, but all of them reported that they did not produce during 1938.

As in former years the Carson Black Lead Co. shipped amorphous graphite from its mine near Carson City, Nev., to Oakland, Calif., for use in graphite paint. A somewhat similar operation is conducted by the Detroit Graphite Co., L'Anse, Mich. The leading manufacturer of artificial graphite is the Acheson Graphite Corporation, whose plant is at Niagara Falls, N. Y.

The Bureau of Mines is not at liberty to publish figures of graphite production.

Imports of graphite declined sharply in 1938, aggregating only 17,005 short tons valued at $372,039 compared with 29,593 tons valued at $752,315 in 1937 and 24,171 tons valued at $566,662 in 1936. Exports were 983 tons valued at $112,443 compared with 1,514 tons valued at $163,331 in 1937 and 816 tons worth $114,847 in 1936. Imports of leading items in 1938 (1937 figures in parentheses) were: Artificial graphite, 500 short tons valued at $19,870 (802 tons, $31,562); natural amorphous, 14,676 tons, $247,789 (25,354 tons, $512,162); Ceylon lump and chip, 41 tons, $3,074 (482 tons, $41,499); dust, 168 tons, $10,643 (321 tons, $17,600); and flake, 1,620 tons, $90,663 (2,634 tons, $149,492). All artificial graphite comes from Canada. In 1938 Mexico supplied two-thirds of the imports of natural amorphous graphite; shipments from Ceylon and Japan (Chosen) to this country were much less than in 1937. Imports of dust were furnished by Ceylon and Madagascar in roughly equal proportions. As usual most of the flake graphite was from Madagascar or France.

Under the trade agreement with the United Kingdom, effective January 1, 1939, the duty on amorphous graphite was cut from 10 percent to 5 percent ad valorem and that on Ceylon lump, chip, and dust likewise was halved, from 30 percent to 15 percent ad valorem. Effective June 15, 1936, the rate on flake graphite was reduced under the trade agreement with France; the previous rate, under the tariff act of 1930, was 1.65 cents a pound and the new rate is 30 percent ad

Digitized by Google

valorem with the proviso that this shall not be less than 0.825 nor more than 1.65 cents per pound.

Prices of graphite tended to be somewhat lower in 1938 than in 1937, but the quotations did not differ greatly from those reported in Minerals Yearbook, 1938.

*World production of natural graphite, 1910–14, 1925–29, 1930–34 (5-year averages), and 1935–37, in metric tons*

Small amounts of graphite are produced in many countries, from Greenland (60 metric tons in 1937) to the Union of South Africa (63 tons in 1937). A half-dozen countries or more are fairly large producers, but in recent years none of them has challenged the supremacy of Ceylon and Madagascar as producers of high-grade graphite. Of a world total annual output of 200,000 tons, the U. S. S. R. recently has been credited with over 40 percent; Germany and Austria (combined), over 20 percent; Chosen, 20 percent; and Mexico, 5 percent. However, the bulk of the product in these countries is low-priced amorphous graphite, much of which is used only locally. Although the tonnage mined in Ceylon and Madagascar seldom exceeds 15 percent of the world total the value of their outputs is probably at least half the world total.

## GREENSAND

The domestic production of greensand in recent years has been in New Jersey, chiefly by 3 companies although 1 or 2 other producers are more or less active. Shipments of refined greensand decreased in 1938 to 6,576 short tons valued at $152,000 compared with 9,734 tons worth $211,000 in 1937; the annual average for the 1925–29 period was 12,715 tons valued at $197,200. The valuation figures are partly estimated because a substantial part of the output is further processed by the producers and sold as water-softening compounds worth up to $115 a ton. Formerly considerable quantities were used for fertilizer, but this use has almost disappeared. The best grade of refined greensand (carload lots, screened and bagged) has been quoted in Engineering and Mining Journal at $20 per short ton, f. o. b. cars, for several years.

Properly processed greensand occupies a unique position in the water-softener field. Owing to its extremely high rate of exchange, it softens water as rapidly as the water can be forced through it. Since no synthetic zeolite yet seems to have approached this speed of reaction and since its speed of regeneration is equally great, greensand largely supplanted products prepared by a fusion synthesis. The historical development of the zeolite or base-exchange principle and additional information on the properties of greensand and other zeolite softeners are discussed briefly in Bureau of Mines Bulletin 328, which contains an annotated bibliography of the literature published before 1930.[8] This bulletin is out of print but may be consulted in libraries of most of the large cities of the United States. Additional information may be found in the trade literature issued by the filter companies that supply the processed materials.

Natural zeolites comprise a group of silicate minerals all of secondary origin and usually found in seams or cavities of basic igneous rocks. This group includes apophyllite, stilbite, chabazite, analcite, and natrolite, which, however, are of interest only to the mineralogists and are seldom, if ever, found in minable quantities.

Most clays are capable of some zeolitization, and a claylike material from one of the Faroe Islands (Denmark) flakes down and is suitable for use in water softeners.

Indicative of the growing market for water-softening chemicals are the Bureau of Census reports of shipments of water-softening apparatus for domestic use, which have increased steadily from a monthly average of 273 units in 1933 to 1,066 in 1937; the monthly average for 1938 was 1,027 units.

## KYANITE, ANDALUSITE, AND DUMORTIERITE

Notwithstanding the depressed condition of many of the consuming industries, domestic production of kyanite showed further progress in 1938, although imports of "kyanite and sillimanite" decreased to 3,964 short tons valued at $32,458 compared with 7,674 short tons and $79,410 in 1937, the first year for which statistics are available. British India has been almost the only foreign source of kyanite or its allied minerals sillimanite, andalusite, and dumortierite. However,

[8] Shreve, R. N., Greensand Bibliography to 1930 (Annotated), with a Chapter on Zeolite Water Softeners: Bureau of Mines Bull. 328, 1930, 78 pp.

Digitized by Google

kyanite schists in the U. S. S. R. are reported [9] to be suitable for refractories, and in December 1938 the Bureau of Mines was asked to advise regarding possible markets in the United States for South African andalusite averaging 57 percent $Al_2O_3$ and containing 1.1 percent $Fe_2O_3$ and 0.1 percent MnO. These deposits, which were described in a bulletin [10] of the Department of Mines at Johannesburg, occur in the Zeerust and Marico Districts of western Transvaal, some of the best material being found along the Doorn River (part of the Marico drainage system) where it flows over the lowest horizons of the Pretoria series.

According to a report of the Imperial Institute (Bull. 36, pp. 493–498) recent discoveries in Nyasaland suggest that alternative supplies of kyanite may be available from that country. Deposits in British East Africa may be regarded as potential sources, although perhaps at present material could not be landed at United Kingdom ports at less than £5 a ton. Samples of good-quality kyanite have been received at the Imperial Institute from Kenya, and the producer claimed that he could make shipments at the rate of 100 tons a week. In Western Australia kyanite is abundant in the Chittering Valley 40 miles from Perth.

The leading domestic producer of kyanite, Celo Mines, which boosted capacity to 15 tons of kyanite concentrates a day, operated steadily during 1938 although at a reduced rate owing to the shrinkage in sales to refractory manufacturers. Further major changes in the flow sheet are contemplated in order to yield some entirely new products, including an especially low-iron kyanite that may be used directly in electrical porcelain glazes and as an ingredient in glass. Byproduct garnet has become an important credit item, and experimental work has been conducted to devise means of utilizing the mica which, however, is mostly biotite. The quartz at this property is thermally luminescent, and it is thought that some day this peculiar phenomenon may find a useful application.

The Phosphate Recovery Corporation pilot mill on Baker Mountain near Pamplin, Va., was remodeled again. Owing to the losses experienced by straight gravity concentration, wet tabling has been supplemented by froth flotation, and bleaching tests have been made to lower further the iron content of material drawn from certain parts of the deposit.

At Clarkesville, Ga., the Southern Mining & Milling Co. produced kyanite from schists by its mulling process recently patented (U. S. Patent 2105597, January 1938) by Philip S. Hoyt. E. C. Noble, New Florence, Mo., reported that he was building a mill near Clarkesville, Ga., to produce both kyanite and vermiculite from schist. B. J. Lachmond shipped a few cars of kyanite from Henry Knob, S. C. Other domestic producers include the Vitrefrax Corporation of Los Angeles with mines at Ogilby, Calif., and the Tillotson Clay Products Co., Los Angeles (mines in California and Nevada). The latter organization has produced andalusite near Hawthorne, Mineral County, Nev.

The leading andalusite mine in the world, however, is operated by Champion Sillimanite, Inc., in the White Mountains, Calif. This

Digitized by Google

company is a subsidiary of the Champion Spark Plug Co., Detroit, Mich., whose laboratory-porcelain and thermocouple protection-tube business has been sold to the Coors Porcelain Co., Golden, Colo. The company also has a dumortierite property in Oreana, Nev., which is credited with a total output of 4,500 tons up to and including the 1938 production. This figure is probably also the aggregate world output to date. The andalusite mine is high on the west slope of White Mountain Peak above the little town of Laws, Inyo County, Calif., close to the Nevada line and not far from Bishop, Calif. The mineral occurs in irregular lenses largely on the footwall of the quartz monzonite dike. The original outcrop was on the walls of a cliff so steep that miners at first had to be lowered on ropes. The ore is hand-sorted and transported by muleback to shipping bins 3 miles away and 3,000 feet lower.[11]

Production figures for kyanite and related minerals are not available.

The function of dumortierite in spark-plug insulators and electrical porcelain is to increase the electrical resistivity and widen the burning range. Dumortierite refractories swell slightly when fired; however, contrary to published statements dumortierite is not used in spark-plug cores to overcome any tendency of andalusite to sag but because it is almost indispensable in the product. Dumortierite is valuable for use in such places as the spout for a glass tank, where it seems to resist the eroding effect of the glass remarkably well.

Prices of kyanite were reduced at the beginning of 1939. For regular refractory grades the cut was as much as 40 percent; for high-grade white-burning products it was less. Throughout most of 1938 Celo Mines was offering a 98-percent kyanite, white-burning concentrate, calcined and ground to 325-mesh and carrying only about 0.1 percent $Fe_2O_3$.

## LITHIUM MINERALS

The Bureau of Mines has resurveyed the Nation's resources of low-grade lithium ores and has developed methods for concentrating them and extracting lithium compounds, thereby demonstrating that raw-material supplies afford no handicap to rapid expansion in commercial utilization of the metal and its salts. Only a few years ago lithium was thought to occur only in small, widely scattered deposits and consequently seemed destined to remain one of the rarer elements, but now it may be regarded as one of the cheaper, readily available metals. In 1938 an interesting report [12] on lithium occurrences in Maine and Massachusetts was published. A good description of the Harding mine in Taos County, N. Mex., which produced as much as 12,000 tons of lepidolite before it closed in 1930, has been issued by the State Bureau of Mines and Mineral Resources.[13] Although the ore shoot that was worked in the past may be mined out, a well-conducted exploration program probably would disclose other shoots that could be exploited.

The mine production of lithium minerals in the United States decreased sharply in 1938, but this was more than offset by the recovery of lithium from a new and heretofore unsuspected source,

Digitized by Google

namely, as a byproduct of the complex brine-refining operations in California (at Searles Lake) which yield potash, sodium sulfate, soda ash, and borax as coproducts. The total production of lithium compounds, as given by producers to the Bureau of Mines, aggregated 892 short tons valued at $329,088 compared with 1,357 tons valued at $36,206 in 1937 and 1,241 tons worth $34,273 (revised figures) in 1936. Although the tonnage was much less in 1938 than in earlier years, the value was almost 10 times as great because the average lithium content was increased greatly owing to inclusion of the lithium phosphate recovered at Trona, Calif., by the American Potash & Chemical Corporation.

Three producers reported shipments of lithium ores from South Dakota in 1938. Amblygonite, lepidolite, and spodumene were shipped from Keystone, Pennington County, where the Etta mine was operated by the Maywood Chemical Works and the Ingersol mine by the Black Hills Keystone Corporation. Amblygonite was also shipped from the Tinton mine of the Black Hills Tin Co., at Tinton. Small quantities of lithium ores were produced from other properties in South Dakota and North Carolina but not shipped.

*Lithium compounds produced and shipped in the United States, 1929–38*

| Year | Number of producers | Short tons | Value | Year | Number of producers | Short tons | Value |
|---|---|---|---|---|---|---|---|
| 1929 | 2 | (1) | (1) | 1934 | 5 | 719 | $20,980 |
| 1930 | 5 | 1,797 | $56,327 | 1935 | 4 | 1,154 | 26,834 |
| 1931 | 2 | (1) | (1) | 1936 | 6 | [2] 1,241 | [2] 34,273 |
| 1932 | 2 | (1) | (1) | 1937 | 7 | 1,357 | 36,206 |
| 1933 | 6 | 504 | 12,997 | 1938 | 4 | 892 | 329,088 |

[1] Bureau of Mines is not at liberty to publish figures.
[2] Revised figures.

The first production of lithium ore in Canada came from deposits at Bernic Lake, Manitoba, in 1937. The entire output (mainly lepidolite and spodumene) valued at $1,694 was shipped to the United States. The Canada Bureau of Mines reported a discovery of spodumene near Falcon Lake 85 miles east of Winnipeg, which carries enriched portions that are considered minable. Lepidolite from the Silver Leaf deposits in Manitoba contains substantial quantities of cesium and rubidium. Amblygonite, as well as spodumene and lepidolite, was being prospected in 1938 in the Lac du Bonnet district in Quebec.

South-West Africa and France are the largest producers of lithium ores outside of the United States. Formerly amblygonite was mined extensively in the Spanish Peninsula, but in recent years shipments from Spain and Portugal have virtually ceased. During the first half of 1938 no lepidolite was produced in South-West Africa, whereas in the similar period of 1937 there was an output of 745 long tons averaging 3.75 percent $Li_2O$; however, the output of amblygonite (8.5 percent $Li_2O$) jumped to 170 tons compared with 35.7 tons. These minerals, all produced at Jooste lithium mine, are exported to the United Kingdom, France, Germany, and the United States. During the entire year of 1937 the output of lepidolite was 1,030 tons and of amblygonite 220.7 tons. In 1936 no amblygonite was shipped, but the lepidolite output was 852 tons. Export valuations for

Digitized by Google

lepidolite declined in 1938 to less than £2 10s. (about $12.50) a long ton as against £2 15s. in 1937; the reported value for amblygonite increased slightly to almost £10 or about $50 a ton.

The increase in the use of lithium chloride as an air desiccant has been disappointingly slow. Although this outlet and various other uses of the salts or the metal itself continue to afford promise of much greater development, interest recently has centered more upon ceramic uses. According to Betz [14] the chief advantages of lithium in ceramic formulas are: (1) It is a powerful flux especially in conjunction with feldspar; (2) in certain glasses of low thermal expansion it permits the use of much less alkali; (3) it enables the production of glasses of high electric resistance and desirable working properties; (4) a high $Li_2O$ content aids in producing glasses that transmit ultraviolet light; (5) it has a strong mineralizing effect in ceramic bodies; (6) replacing PbO by $Li_2O$ reduces the tendency for a glaze to vaporize; and (7) it lowers the maturing temperature and greatly increases the fluidity and gloss of enamels and glazes.

Spodumene expands in whiteware bodies, and if properly controlled this expansion may offset shrinkage and other production troubles. Lepidolite hardens and toughens clear glass and lowers the expansion coefficient. Formerly lepidolite was used chiefly in place of cryolite in opal and white glass, but recently it has been receiving attention as a constituent of heat-resisting, low-expansion, and nonshattering glass; it is a powerful flux and brings potash and fluorine as well as lithia and aluminum into the bath.

According to Preston [15] variation in the composition of natural lithium minerals has led to the use of chemically prepared salts in ceramic work; the most important of these is the carbonate, which has wide application in the production of better-quality glazes. Addition of 1 percent or more lithium carbonate to dinnerware and sanitary-ware glazes increases gloss, and in electrical porcelain this compound produces a glaze of high strength and weather resistance. In glazes, as well as in glassmaking, the high fluidity imparted by lithium additions increases the workable range of other desirable addition agents. To obtain a similar degree of fluidity requires smaller proportions of lithia than of potash or soda. An interesting development is the use of molten lithium nitrate as an etching agent on glass. Glasses of high lithia content possess greater transmission of ultraviolet light.

Single crystals of lithium fluoride are grown up to 2,200 grams in weight. These afford an excellent substitute for optical fluorite which is becoming scarce, especially in large sizes. In 1938 the Harshaw Chemical Co.[16] undertook to manufacture these new crystals, employing the technique originally developed in the physical laboratories at Harvard University and the Massachusetts Institute of Technology. Large crystals of rock salt and sodium nitrate also are produced for optical uses.

## MEERSCHAUM

Apparently world supplies of crude meerschaum in recent years have come exclusively from the Eskishehir deposits in Turkey. Imports into the United States in 1938 were 3,559 pounds valued at $9,221

[14] Betz, Geo. C., Lithium Minerals and Compounds in Ceramics: Jour. Am. Ceram. Soc., vol. 21, No. 5, 1938, pp. 189–191; Chem. Abs., vol. 32, No. 13, July 10, 1938, p. 5169.
[15] Preston, E., Lithium in Glass and Ceramics: Foote-Prints, vol. 11, No. 1, July 1938, pp. 1–15.
[16] Industrial and Engineering Chemistry, News Ed., vol. 16, No. 21, November 10, 1938, p. 584.

Digitized by Google

compared with 3,687 pounds worth $12,681 in 1937. The average import valuation of $2.59 in 1938 compares with $3.44 in 1937, a minimum of $1.36 in 1924, and a maximum of $4.09 in 1934.

According to a recent report to the Bureau of Mines a commercially promising deposit of meerschaum has been found in the State of Washington. A few scattered deposits had been known previously in the United States. Domestic production has totaled perhaps 1,000 tons, chiefly from a mine near Sapillo Creek, N. Mex., which ceased to be worked about 1914.

## MINERAL WOOL

Notwithstanding a further large increase in productive capacity and some improvement in contracts for residential and certain other kinds of building construction, the output of mineral wool in the United States apparently dropped in 1938. Actual figures are not available, but those in close touch with the industry have estimated that the reduction was 20 percent or more compared with 1937. A leading development was the construction of a huge new plant by Johns-Manville Corporation near Long Beach, Calif. The raw material for this plant is wollastonite mined in Rademacher district near Randsburg. Among other new plants are those of the Edwards Insulation Co., Temple, Tex.; the Northern Rock Wool Co., Pontiac, Mich.; the P. J. Sonner Burner Co., Winfield, Kans.; the Kentucky Stone Co., Mullins, Ky.; and the Ohio Valley Rock Asphalt Co., Summit, Ky. Several existing plants were modernized and expanded; by the simple process of adding another tap hole, the capacity of individual cupolas has been doubled. J. R. Thoenen, of the Bureau of Mines, estimates that there are about 160 cupolas capable of making rock or slag wool in the United States; at least 60 companies operate 70 or more plants in various parts of the country. Productive capacity is approximately 600,000 tons annually, whereas the output in 1938 did not exceed 400,000 tons and possibly was much less. It is estimated that the total output is now divided almost evenly among the three types of products—nodulated (granulated) wool, loose wool, and batts.

The only available statistics of the mineral-wool industry are the biennial figures of the Bureau of the Census, which has reported a total value of $8,279,374 for the production of "mineral wool (other than asbestos) for building insulation" in 1937 compared with $7,786,285 (revised figures) in 1935, $1,714,171 in 1933, $2,873,230 in 1931, and $2,377,324 in 1929. A break-down of the latest figures shows an increase in value for rock wool from $3,361,446 in 1935 to $4,989,117 in 1937 and for slag wool from $1,184,946 to $2,474,295, whereas for "other" mineral wool there was a sharp decline from $3,239,893 in 1935 to only $815,962 in 1937. Glass wool, however, was included in still another blanket classification and the exact nature of the material covered in this category is not revealed.

The production of glass wool and fibers has increased greatly, and their uses have become more diversified. Of wide interest is the employment of glass "mulching wool" for the winter protection of plants. Supplied in strips, 2 inches thick, like cotton batting, it affords better protection than snow, weighs only one-fourth as much, and lasts 3 winters. In 1938 the two domestic producers of glass fibers, the Corning Glass Works and the Owens-Illinois Glass Co.,

Digitized by Google

combined their business in the glass-fiber field under the name of the Owens-Corning Fibre Glass Co., a jointly owned but otherwise independent corporation.

## MONAZITE

Imports of monazite into the United States increased slightly in 1938 to 456 short tons valued at $18,210, of which 339 tons valued at $14,402 were from British India, 110 tons valued at $3,421 from Brazil, and 7 tons valued at $387 from the United Kingdom. In 1937 the imports were 336 tons valued at $13,579 compared with 607 tons and $25,324 in 1936. No domestic output has been recorded since 1925. Prices, as reported by the Engineering and Mining Journal, remained unchanged at $60 to $75 a short ton (basis, 8 percent $ThO_2$) until late in the year when they narrowed to $60 to $70 a ton.

## OLIVINE

Dunite deposits of commercial importance are found in California, Washington, and North Carolina. The North Carolina deposits are the largest and contain the most adaptable material. They contain probably 50 to 100 million tons of olivine suitable for the manufacture of forsterite refractories and recently have produced as much as 600 tons a month, a figure that could promptly be increased to keep pace with any reasonable expansion in demand. Exact figures are not available, but shipments in 1938 declined slightly, being estimated at less than 2,000 tons. There are two quarries, both in Jackson County, N. C.

Greaves-Walker and Stone [17] have summarized available information on olivine and reported their successful search for suitable binders for olivine refractories.

## SERPENTINE

Attractively colored and veined serpentine is marketed as verde antique for building trim and various ornaments. Chips may be used in terrazzo or sold as roofing granules. Recently, however, the Bureau of Mines has received a number of inquiries as to possible other uses, especially for ground serpentine.

Enormous quantities of serpentine, much of it pulverized into an almost impalpable powder, are blown out of the chrysotile asbestos mills in Canada and Vermont. However, as yet, asbestos dust has found only a limited use. It has been employed in conjunction with short-fiber asbestos in various cements and to a very small extent as a filler in miscellaneous products. Recent inquiries seem to be regarding possible use of the material as a refractory, although, as has been pointed out frequently, ordinary serpentine is not a particularly high-melting material and suffers from the further disadvantage of containing much combined moisture that is driven off at a relatively low temperature. Moreover natural serpentine rarely approaches the theoretical formula, $3MgO.2SiO_2.2H_2O$ with 43 percent MgO. Ordinarily it contains 2 to 8 percent iron oxide and substantial quantities of silica, alumina, and other impurities. Both because of these impurities and because of the relatively large content of combined water, it would seem impossible to substitute serpentine success-

[17] Greaves-Walker, A. F., and Stone, R. L., The Production of Unfired and Fired Forsterite Refractories from North Carolina Dunites: North Carolina State Coll. Eng. Exp. Station Bull. 16, September 1938, 123 pp. (Abstracted in Bureau of Mines Mineral Trade Notes, vol. 8, No. 2, Feb. 20, 1939, pp. 19–20).

Digitized by Google

fully for other magnesium silicate minerals of somewhat similar composition, such as olivine (which is anhydrous), talc ($3MgO.4SiO_2.H_2O$), or even soapstone (an impure talc). Additional information as to possible uses for serpentine therefore will be awaited with interest.

Another inquiry relates to antigorite, a form of serpentine that has a platy rather than fibrous or asbestiform structure. As reported in the magazine Asbestos (December 1938, p. 38), a substantial deposit of relatively pure antigorite has been located in California, near Stockton. The same deposit also contains a mixture of pure antigorite and short-fiber asbestos that could be mined commercially.

## STRONTIUM MINERALS

Available information on the strontium industry has been summarized in recent volumes of Minerals Yearbook; a general review appeared in Minerals Yearbook, 1935 (p. 1232). Bureau of Mines Economic Paper 4, Strontium from a Domestic Standpoint, is somewhat out of date but may be purchased from the Superintendent of Documents, Government Printing Office.

Strontium salts, notably nitrate, are used in the United States almost exclusively in pyrotechnics, the chief outlet being the red flares used by railway companies and truckers as warning signals.

A number of firms have indicated to the Bureau of Mines that they are possible producers of strontium minerals, and domestic resources of celestite are undoubtedly large. During 1938 the Bureau of Mines received many inquiries as to possible markets for strontianite, which recently seems to have been found in Gunnison County, Colo., near Parlin and in New Mexico. No domestic production of strontium ore has been reported since 1918, and domestic needs are supplied by imports. However, the Mudrite Products Co. of Houston, Tex., has recently mined impure celestite near Sweetwater, Tex., and ground it at Nacogdoches, Tex., for use as a new oil-well drilling mud admix. An analysis shows over 82 percent $SrSO_4$.

Except for an unimportant increase for precipitated carbonate, imports of strontium ores and compounds declined sharply in 1938. Imports for 1938 (1937 in parentheses) follow: Strontianite and (chiefly) celestite, 552,868 pounds valued at $2,824 (5,636,570 pounds, $20,877); strontium nitrate, 364,362 pounds, $23,921 (609,488 pounds, $40,243); and precipitated carbonate (this classification nominally includes oxide as well), 82,859 pounds, $8,502 (44,579 pounds, $4,610).

## TOPAZ

Topaz is best known as a gem mineral but is not uncommon as a minor constituent of granites. Colorless topaz bears a superficial resemblance to quartz and is even more likely to be confused with phenacite, the illusive beryllium mineral that thus far has not been found in commercial quantities although often reported. Topaz is usually, but not always, harder than quartz and differs from quartz in that it has perfect basal cleavage.

A unique occurrence of massive topaz recently was discovered in the Brewer gold mine near Jefferson, Chesterfield County, S. C. According to a Geological Survey report [18] this deposit contains an

[18] Pardee, J. T., Glass, J. J., and Stevens, R. E., Massive Low-Fluorine Topaz from the Brewer Mine South Carolina: Am. Mineral., vol. 22, No. 10, October 1937, pp. 1058–1064.

Digitized by Google

enormous quantity of topaz unusually fine-grained in texture and low in fluorine. The hardness is only 7 (usually 8), and the specific gravity is the lowest ever recorded for topaz, probably owing to the low fluorine content (13.23 percent F). The percentage of silica is only 33, and that of $Al_2O_3$ is reported as 56.76 (some of which, however, represents $AlF_3$).

Attention has been given to commercializing the material, possibly as a refractory.

## VERMICULITE

An outstanding development in the vermiculite industry in 1938 has been the progress in the utilization of smaller sizes. In Minneapolis, which has long been a leading market and where three expanding plants are now producing house fill, important sales of vermiculite plasters have been made recently. The vermiculite replaces the fiber and part of the sand, and the product has good heat- and sound-insulating properties. Of special interest is its use in school buildings to prevent transmission of noise by the steel framework. The fire resistance of such plasters is superior to that of plasters made from larger pellets of vermiculite which sometimes expand further when strongly heated, thereby causing cracks. Hitherto, sizes smaller than those used for loose house fill (minus 3- plus 14-mesh) have been difficult to dispose of, often having been thrown away at the mines, but other new uses are developing for finer sizes in conjunction with fireclay and bentonite for special refractories, including combustion chambers for oil-burner equipment. Visitors to the San Francisco World Fair will see expanded vermiculite sparkling in the walls of the buildings. To impart a distinctive finish to the 200,000 square yards of exterior stucco 140 tons of vermiculite, especially heat-treated to a bright golden color, was applied while the cement stucco was still wet.

These new uses failed to offset the decline in demand for home insulation, previously noted for mineral wool.

*Vermiculite sold or used in the United States, 1936–38*

| Year | Short tons | Value | |
|---|---|---|---|
| | | Total | Average per ton |
| 1936 | 16,933 | $185,787 | $10.97 |
| 1937 | [1] 26,556 | [1] 260,664 | [1] 9.82 |
| 1938 | 20,700 | 192,000 | 9.28 |

[1] Revised figures.

In 1938 raw vermiculite was produced commercially in the United States by two companies in Montana and one each in Colorado and Wyoming. Another concern made trial shipments from North Carolina. Although all the mining companies sell cleaned raw vermiculite, most of them have acquired one or more expanding plants so that they can sell their product more directly to the consumer. Prices of the raw material are approximately $12 f. o. b. Western mines and nominally $6 or $7 a ton f. o. b. North Carolina.

| Summary, 1931–38 | 1421 |

The outstanding feature of the mineral industry of the United States in 1938 was a decline of 8 percent in the number of men employed, accompanied by an even more pronounced reduction in the number of man-hours worked—22 percent. Fortunately, this loss in employment was accompanied by a decreased number of accidents to employees. The reduction in accidents was proportionately greater than the decline in man-hours, so that the accident-frequency rate for a given exposure to occupational hazards was slightly more favorable in 1938 than in 1937.

Of the 21 branches of the mining industry for which separate figures have been compiled, 16 reported a decrease in the number of men employed and 5 showed virtually no change or possibly a slight gain in the number of workers. The five classes of operations that showed little or no loss in the number of workers were gold and silver mines, cement mills and quarries, limestone quarries, trap-rock quarries, and nonmetallic-mineral mines.

These general statements are based upon a comparison of reports covering identical plants for the 3 years 1936–38, inclusive. The plants selected were those for which reports for 1938 had been received in time for review in the current issue of Minerals Yearbook. The reports cover from 35 to 97 percent of the number of men employed in the 21 branches of the mineral industries to which the figures relate. Reports for bituminous-coal mines, the largest group of operations, covered 60 percent of the total number of workers.

The following table shows the number of men employed from 1936 to 1938, inclusive, in each of the 21 branches of the mining and allied industries. All figures for 1936 are complete and final, as are the 1937 figures for quarries, coke ovens, iron mines, copper mines, and anthracite mines. All other figures for 1937 and all figures for 1938 are subject to revision.

[1] Subject to revision.

A summary table showing number of men employed, number of man-days worked, number of men killed by accidents, and yearly fatality rates for the mining and quarrying industries from 1911 to 1935 was published in Minerals Yearbook, 1937 (p. 1454). The following table contains similar data for 1931 to 1938, inclusive, not only

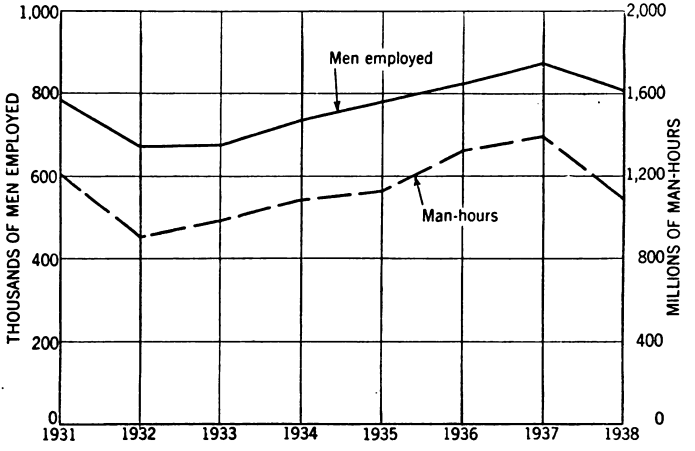

FIGURE 1.—Trend of employment in the mineral industries of the United States, 1931–38.

for mines and quarries but also for coke ovens, ore-dressing plants, smelters, and auxiliary works associated with ore-dressing plants and smelters. In addition, the table contains figures showing the number of nonfatal injuries and the nonfatal-injury rates. Figure 1 shows the trend of employment in the mineral industries since 1931, and figures 2 and 3 indicate the trend of accidents and accident rates, 1931–38.

[1] Subject to revision.

## EMPLOYMENT AND ACCIDENTS

### BITUMINOUS-COAL MINES

*Employment.*—The number of workers and number of man-hours worked in bituminous-coal mining, which employs more men than all other branches of the mineral industry of the United States combined, dropped in 1938 compared with 1937. Although final figures

Digitized by Google

are not available for either year, reports thus far received from producing companies representing 60 percent of the industry indicate that the number of employees, which was 482,500 in 1936, rose to 507,000 in 1937 then fell to 469,000 in 1938—a loss of 30,000 or more employees in 1938 from the number working in 1937. The loss in man-hours worked at the mines was even more severe. The indicated number of man-hours worked in 1938 was 527 million, a loss of 24 percent from the tentative figure of 690 million for 1937 and of 21 percent from the final figure of 670 million for 1936. The corresponding drop in production of coal below 1937 was about 23 percent. An average of 160 workdays per man is indicated by the reports for 1938—a loss of 35 days per man compared with 1937.

*Accidents.*—The number of accidents to the mine workers in 1938 dropped sharply to 39,000 disabling injuries and 900 fatalities from 54,000 disabling injuries and 1,198 fatalities in 1937. The accident-frequency rate per million man-hours of employment or exposure to hazard was 75.7 compared with 80.3 in 1937 and 77.0 in 1936. Should these figures stand without material change when final figures for 1937 and 1938 become available, they will show that the safety record in 1938 was more favorable for the coal-mine workers than in any year since 1930 when, for the first time, complete reports of fatal and nonfatal injuries were collected for the industry.

### ANTHRACITE MINES

*Employment.*—Although the number of employees at anthracite mines in Pennsylvania decreased only slightly (about 4 percent) in 1938 according to final reports for 1937 and an estimate based upon incomplete returns from the operating companies for 1938, a more severe decline (about 15 percent) occurred in the total man-hours worked in 1938. According to final and complete reports for 1937, 99,085 men were working at the mines, preparation plants, and breakers in that year. Preliminary returns that cover about 62 percent of the industry indicate that this number apparently declined to about 95,000 in 1938, but final returns may raise the figure slightly. A total of 116 million man-hours were worked in 1938, according to present estimates, compared with 136 million man-hours in 1937. The average period of employment was only 174 days per worker in 1938, a loss of 15 work days per man from the 1937 average.

*Accidents.*—The recession in employment at anthracite mines in 1938 was accompanied by a reduction in the number of injuries resulting from accidents to the workers. However, the decreased number of accidents did not keep pace with the decline in employment; therefore, the accident rate per unit of employment was less favorable than in 1937. The rate for fatal and nonfatal accidents in 1937 was 115.2 per million man-hours of work; this rate increased slightly in 1938 and, according to preliminary data, reached 118.9 per million man-hours. Both years, however, had more favorable rates than 1936, when the rate was 123.4.

### IRON-ORE MINES

*Employment.*—Measured by the number of man-hours worked, employment at iron-ore mines decreased decidedly in 1938. The number of man-hours of work performed declined 39 percent, com-

Digitized by Google

pared with 1937, according to reports now available which cover about 92 percent of all employees in the industry. The drop in man-hours worked was more severe for open-cut mining (57 percent) than for underground operations (35 percent). The decline in number of employees was much less severe. A 22-percent reduction was indicated in the total number of workers—the net result of a decline of 12 percent for underground employees, 48 percent for men at open-cut mines, and 16 percent for surface employees. A loss was also reported in the number of workdays per employee in 1938, the figure being tentatively set at 194 days in 1938 compared with 249 days in 1937 and 232 days in 1936.

*Accidents.*—Accidents were strikingly fewer, and in proportion to employment in 1938, only about one-third as many men were injured as in 1937. The tentative rate for 1938 shows only 16.1 fatal and nonfatal injuries per million man-hours worked compared with 30.8 in 1937 and 25.9 in 1936.

### COPPER MINES

*Employment.*—Although much copper is produced by mines whose ores are valuable chiefly for some other metal, the employment and accident figures of the Bureau of Mines cover only mines whose ores are valuable primarily for their copper content. It is manifestly impossible to segregate employment and accident data for a mine according to the various kinds of metal contained in the ores that the mine produces. Mines whose chief output was copper employed approximately 17,800 men in 1938, according to reports from companies whose employees represent about 91 percent of the total number of men working at all copper mines. This indicates a decrease of 16 percent from the number of men employed in 1937 but a gain of 26 percent over 1936. The prevailing working time was 8 hours a day, and the total number of man-shifts worked at all mines averaged 243 workdays per man, a loss of 64 days per man from 1937.

*Accidents.*—Marked progress was made in the prevention of accidents in copper mines in 1938, the accident-frequency rate being much lower than that for either 1937 or 1936. The indicated rate for 1938 was 56.3 per million man-hours of employment compared with 95.9 for 1937 and 81.9 for 1936. The actual number of injuries to the employees in 1938 was considerably less than in 1937 owing mainly to the fact that fewer men were working and partly to the fact that the workyear was shorter in 1938. The reports from the operators showed, however, that accidents decreased faster than employment, hence the improvement shown as a reduction in the accident rate per million man-hours of employment.

### LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

*Employment.*—Measured by the number of man-hours worked, employment at lead and zinc mines in the Mississippi Valley States declined about 25 percent in 1938, according to operating companies' reports to the Bureau of Mines covering about 58 percent of the employees at the mines. On the other hand, the number of men working was only about 9 percent less than in 1937. In contrast, the working force in 1938 represented a gain of 17 percent compared with 1936. The workyear was comparatively short, consisting of

Digitized by Google

only 201 days per man in 1938, according to information now available, compared with a tentative figure of 240 days for 1937 and a final figure of 226 days for 1936.

These figures are for lead and zinc mines only; they do not include data for fluorspar mines in Illinois and Kentucky, which are sometimes combined with lead and zinc mines in the Mississippi Valley States.

*Accidents.*—A small increase was reported in the accident-frequency rate for lead-zinc mines in 1938, but it may not be sustained when complete reports from all producing companies have been received. The estimated rate for 1938 per million man-hours worked, based upon reports thus far furnished, was 61.5 compared with 60.4 for 1937. Both rates are higher than the rate of 54.6 for 1936.

### GOLD AND SILVER MINES

*Employment.*—This group comprises mines that produced ores containing any one or more of the five major metals—gold, silver, copper, lead, and zinc—except mines whose output was valuable chiefly for the copper content of the ore and mines in the Mississippi Valley States operated for lead or zinc. The category therefore includes lead-zinc mines in all States outside of the Mississippi Valley region and mines whose ores, although containing some copper, were valuable chiefly for some other metal. Placer as well as lode mines are included.

From a total of 47,967 employees in 1936 the number rose to an estimated 52,000 in 1937 and remained virtually the same in 1938, according to reports from many, but not all, operating companies. However, the amount of employment per worker was less in 1938 than in either 1936 or 1937, as the smaller number of man-hours shows. The total volume of employment was 93 million man-hours in 1936 and, according to reports now available, about 94 million in 1937 and 91 million in 1938. Each employee, excluding those at placer mines, averaged 259 working days in 1936 compared with an estimated 239 days in 1937 and 241 days in 1938. The average working time per employee at placer operations cannot be given for 1937 and 1938 at this time but was 174 days in 1936.

*Accidents.*—The accident rate for this group of mines has been increasing during the past 3 years. The combined rate for lode and placer mines was 94.8 in 1936 and, according to data now available, increased to 107.8 in 1937 and 111.1 in 1938.

### MISCELLANEOUS METAL MINES

*Employment.*—This group covers all mines whose ores were valuable chiefly for their content of some metal other than gold, silver, copper, lead, zinc, or iron. It therefore comprises mines that produced quicksilver, tungsten, manganese, and various other metals. Approximately 3,600 men were working in mines of this group in 1938, according to information in reports from companies whose workers include about half of all employees at such mines. The number of men working was 22 percent less than in 1937 but 10 percent more than in 1936. The average number of days worked per man was 244 in 1938, indicating a loss of 17 workdays per man compared with 1937, but a gain of 4 days per man compared with 1936.

Digitized by Google

*Accidents.*—The accident-frequency rate for this group of mines was not as favorable in 1938 as in 1937. Present reports indicate that the 1938 rate was 71.9. Reports for 1937 showed a rate of 63.7 and for 1936 of 89.1.

### NONMETALLIC-MINERAL MINES

*Employment.*—The number of men working at nonmetallic-mineral mines in 1938 decreased about 8 percent from 1937. A more serious reduction in employment was indicated by the total number of man-hours worked, which was 14 percent less than in 1937. These declines are based on reports from companies representing about 54 percent of all employees at mines in this group. The total working time for all employees averaged 239 days per man compared with 254 days per man during 1937. Mines in this group comprise all classes of nonmetallic mines, including those that produced phosphate rock, fluorspar, gypsum, salt, sulfur, or any of various other nonmetallic minerals.

*Accidents.*—Accidents in these mines declined also, and the decrease in number of accidents was proportionately greater than that in number of employees. Therefore the accident-frequency rate was more favorable in 1938 than in 1937. Tentative figures show an accident rate of 39.7 for 1938 compared with 47.5 for 1937 and 50.7 for 1936.

### CEMENT MILLS AND QUARRIES

*Employment.*—A slight increase in number of workers was reported for cement mills and quarries in 1938, but there were reductions in the total number of man-hours worked and in the average number of workdays per employee. On the basis of reports from companies representing about 89 percent of the total number of workers, the industry as a whole employed about 27,600 men compared with 27,215 in 1937. The estimated number of man-hours worked was 48 million compared with 56 million in 1937. An average of 236 workdays per man was indicated for 1938, a reduction of 42 days per man from the average for 1937.

*Accidents.*—That progress was made in the prevention of accidents in 1938 was shown by a reduction in the accident-frequency rate from 12.2 in 1937 to 9.7 in 1938. This low accident rate for cement mills and quarries was the most favorable one reported by any branch of the mineral industry in 1938 except byproduct coke ovens, whose rate was 7.5.

### MARBLE QUARRIES

*Employment.*—Reports from companies representing about 88 percent of the total number of men working in and about marble quarries showed that the entire industry employed approximately 3,400 men in 1938, a reduction of about 7 percent from the 3,647 men employed in 1937. The total number of man-hours worked declined 5 percent to 6.5 million man-hours in 1938 from 6.9 million man-hours in 1937. The loss of 7 percent in number of workers and of only 5 percent in man-hours worked indicated a slight gain for the average worker in the number of workdays available during the year; the working time averaged 235 days per man in 1938 compared with 230 days per man in 1937.

*Accidents.*—In spite of a slight loss in total man-hours of employment accidents increased, both in number and in relation to volume

Digitized by Google

of employment. Tentative figures show an accident-frequency rate of 58.3 per million man-hours worked in 1938 compared with 50.9 in 1937.

### SLATE QUARRIES

*Employment.*—Reports representing approximately 71 percent of all men employed at slate quarries in the United States indicate that the industry had 2,600 employees in 1938, or 15 percent less than in 1937. This decline in the number of employees was accompanied by a larger decline in the number of man-hours worked. Tentative figures show a total of 4.1 million man-hours of employment, a reduction of 32 percent from the 6.0 million man-hours in 1937. A large reduction also was reported in the average working time per man, which fell from 232 days in 1937 to 186 days in 1938.

*Accidents.*—The decline in number of accidents in 1938 was not as great as the drop in employment, hence the accident-frequency rate increased from 56.9 in 1937 to 62.1 in 1938.

### TRAP-ROCK QUARRIES

*Employment.*—There was virtually no change in the number of men working at trap-rock quarries in 1938 compared with 1937. Moreover, only a slight reduction (about 4 percent) was indicated in the number of man-hours worked in 1938. The industry employed 2,806 men in 1937, and tentative reports show 2,770 men employed in 1938. Measured in man-hours, employment was 4.3 million in 1938 compared with 4.5 million in 1937. The average working time per man was 192 days in 1937 and apparently did not change in 1938.

*Accidents.*—The accident-frequency rate dropped notably in 1938 from the strikingly high figure for 1937, the tentative rate for 1938 being 44.7 per million man-hours compared with the final rate of 75.8 for 1937. The rate for 1936 was 60.3.

### GRANITE QUARRIES

*Employment.*—Reports from operators of granite quarries that employ approximately 56 percent of all men working in the industry indicate a reduction of 8 percent in number of workers and 15 percent in number of man-hours worked in 1938 compared with 1937. The number of workers was 8,961 in 1937 but declined to about 8,200 in 1938, according to reports thus far received. All workers were employed approximately 13.6 million man-hours in 1938 compared with 16.1 million in 1937. Returns now available indicate a total of 210 workdays per man in 1938 compared with 226 days in 1937 and 224 days in 1936.

*Accidents.*—Marked progress was made in the prevention of accidents in 1938, as was shown by a substantial reduction in the number of accidents to employees and in the accident-frequency rate per million man-hours worked. The indicated rate for 1938 was 38.4 compared with 54.0 for 1937 and 52.2 for 1936.

### SANDSTONE QUARRIES

*Employment.*—Losses in the number of men working and the number of man-hours worked were shown by returns from operators

Digitized by Google

of sandstone quarries in 1938. The industry apparently employed a little more than 2,700 men, or about 15 percent less than in 1937, and worked about 3.6 million man-hours—35 percent less than in 1937. The average employee worked 159 days in 1938, the corresponding figure for 1937 being 204 and for 1936, 201.

*Accidents.*—Substantial improvement was reported in the elimination of accidental injuries to employees in 1938. Not only was the actual number of injuries reduced, but also the accident rate was more favorable in relation to volume of employment than in 1937. A tentative rate of 39.4 accidents per million man-hours was shown by reports for 1938 compared with 75.3 for 1937 and 48.2 for 1936.

### LIMESTONE QUARRIES

*Employment.*—This group of operations covers all limestone quarries except those whose product is used chiefly for the manufacture of cement or lime. According to reports from companies whose employees comprise about 49 percent of all workers in the industry, the number of men employed in and about the quarries has remained fairly stationary during the past 3 years. The number of men working is estimated at 24,900 in 1938 compared with 24,789 in 1937 and 24,288 in 1936. Although the number of workers remained about the same, reports thus far received for 1938 indicate that the number of man-hours declined 16 percent below 1937 and 11 percent below 1936. Moreover, the average working period per employee apparently was only about 174 days in 1938, or 28 days less than in 1937 and 20 days less than in 1936.

*Accidents.*—Based on data now available, the accident-frequency rate for limestone quarries increased in 1938 to an estimated 59.8 accidents per million man-hours of employment. In 1937 the rate was 53.9, and in 1936 it was 55.0.

### LIMEKILNS AND QUARRIES

*Employment.*—A drop of 18 percent in number of employees and 27 percent in man-hours worked was indicated for 1938 by reports received from companies operating limekilns and quarries. The working force comprised 8,500 men compared with 10,360 men in 1937, and the period of employment for the industry as a whole was 16.5 million man-hours in 1938 compared with 22.5 million man-hours in 1937. A loss of about 25 working days per employee from the 281 days in 1937 was shown by the reports for 1938.

*Accidents.*—A little progress was made in the prevention of accidents in 1938. The indicated rate for the year is 52.2 accidents per million man-hours worked compared with 54.7 in both 1937 and 1936.

### BYPRODUCT-COKE OVENS

*Employment.*—The number of men employed in the byproduct-coking industry of the United States fell 30 percent and the number of man-hours worked dropped 31 percent during 1938 according to reports from companies that represented approximately 97 percent of the total number of workers at all plants. The average working period was 347 days per man in 1938 compared with 360 days in 1937 and 365 days in 1936. These figures as to the length of the work year

Digitized by Google

do not imply that any given employee worked the number of days indicated; rather they mean that the ovens averaged the indicated number of workdays for the "average" employee. The word "average" here signifies the mathematical mean, or the quotient obtained by dividing the total number of man-days by the total number of oven-days at each operation.

*Accidents.*—The accident-frequency rate for the byproduct-coking industry was more favorable than the corresponding rate for any other major group of the mineral industry, including mines, quarries, coke ovens, and metallurgical plants. Available reports for 1938 indicate an accident-frequency rate for this class of ovens of about 7.5 per million man-hours worked. The excellence of the safety record shown by this low rate may be seen by comparing it with an average rate of 68.9 for all mineral industries combined. The rate for by-product ovens in 1937 was 8.5, and that in 1936 was 8.7.

### BEEHIVE-COKE OVENS

*Employment.*—After increasing from 1,525 men in 1936 to 2,192 men in 1937, the number of employees at beehive-coke ovens in the United States dropped to 1,200 in 1938, according to reports from operating companies whose employees comprise about 62 percent of the total number at this class of ovens. Compared with 1937 the reduction in number of workers in 1938 was 46 percent. The number of man-hours worked at all ovens decreased 63 percent—from 3.28 million in 1937 to only 1.23 million in 1938. The average working time per employee was 150 days in 1938 compared with 213 days in 1937 and 183 days in 1936.

*Accidents.*—The decline in employment was accompanied by a gratifying reduction in the accident-frequency rate and in the actual number of injuries to the employees. An estimate for 1938 indicates an accident rate of 28.4 per million man-hours of employment, compared with the rate of 48.5 for 1937 and 36.0 for 1936.

### ORE-DRESSING PLANTS

*Employment.*—A reduction of about 25 percent in number of employees at ore-dressing plants in the United States was indicated by reports for 1938 from companies that employ approximately 48 percent of the total number of workers in this branch of the mineral industry. The number of man-hours of work done during the year declined 37 percent. Available reports indicate that the total number of men employed in 1938 was 11,400 compared with 15,300 in 1937, and that the man-hours of labor performed totaled 20.5 million in 1938 as against 32.7 million in 1937. The average employee worked 226 days in 1938, or 42 days per man less than in 1937.

*Accidents.*—The accident rate was more favorable in 1938 than in 1937, as was also the actual number of men injured. The tentative rate for 1938 was 27.8 per million man-hours of employment compared with 33.8 for 1937 and 29.7 for 1936.

Digitized by Google

### SMELTERS

*Employment.*—Employment at smelters in the United States declined 19 percent in 1938 when measured by the number of men working and 22 percent when measured by the number of man-hours worked. Reports that covered approximately 88 percent of the workers at all establishments showed that the smelting industry as a whole employed about 14,400 men who worked a total of 35.1 million man-hours in 1938 as compared with 17,900 men who worked 45.2 million man-hours in 1937.

*Accidents.*—The accident-frequency rate for 1938 was more favorable than that for 1937 and about the same as the rate for 1936. The indicated rate for 1938 was 19.9 accidents per million man-hours worked, while that for 1937 was 22.8 and for 1936, 20.6.

### AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

*Employment.*—Employment at ore-dressing plants and smelters, covering employees not directly connected with milling and smelting processes, was somewhat less in 1938 than in 1937 but did not differ materially from that in 1936. An estimate based upon reports from companies representing about 81 percent of all workers indicated a total of 12,200 men employed in 1938, about 2,700 less than in 1937. Final reports for 1936 showed a total of 12,004 men employed. The number of man-hours worked was 29 million compared with 38 million in 1937 and 30 million in 1936. Employment averaged 299 days per man in 1938. In 1937 the average was 320 days per man, while in 1936 it was 318 days.

*Accidents.*—The safety record was more favorable in 1938 than in either 1937 or 1936. The actual number of persons injured was much below that of either 1936 or 1937. According to reports now available, the accident-frequency rate per million man-hours worked was 16.1, which compares favorably with rates of 26.9 for 1937 and 18.5 for 1936.

## SUMMARY, 1931–38

Bureau of Mines records of the number of man-hours of work performed in all branches of the mining and quarrying industries were compiled first for the calendar year 1931. Figures giving this information, as well as accident rates, for 1931–38, are shown in a preceding table.

The period 1931–38 included the year 1932, when employment in the mining and allied industries in the United States reached its lowest point. From 1932 to 1937 employment increased uninterruptedly, but in 1938 some of the previous gains were lost.

If the record for 1932, the low point of the depression, is chosen as a basis for comparison and is represented by an index of 100, the improvement in 1937 and 1938 may easily be seen. With an index of 100 for 1932, the number of men employed in 1937 would be represented by an index of 131, an increase of 31 percent over 1932, and the number of workers on the rolls in 1938 by 120, or 20 percent higher than in 1932. The index of man-hours worked reached 155 in 1937 and dropped back to 121 in 1938.

Digitized by Google

Owing to the greater volume of employment in 1937 and 1938 than in 1932, accidents also increased in number but not as fast as employment, hence the accident-frequency rate declined in relation to volume of employment. The actual number of accidents raised the index to 143 in 1937 and 107 in 1938. As these indexes were smaller than those for man-hours, it follows that the accident rates for 1937 and 1938 were more favorable than the rate for 1932. The accident rate per million man-hours in 1932, the base year, was 77.9. This rate was lowered to 72.0 in 1937 and 68.9 in 1938. The rate for 1938 was the lowest since records of accidents in relation to man-hours of exposure to occupational hazards first became available for the mineral industry of the United States in 1931.
